CHAPTER 1

Introduction

Congratulations on your purchase of one of the most long-awaited computers in the history of computing. The MEGA65 is a community designed computer, based on the never-released Commodore® 65¹ computer, that was first designed in 1989, and intended for public release in 1990. Twenty-eight years have passed since then, but the simple, friendly nature of the 1980s home computers is still something that hasn't been recreated. These were computers that were simple enough that you could understand not just how to work with your computer, but how computers themselves work.

Many of the people who grew up using the home computers of the 1980s now have exciting and rewarding jobs in many companies, in part because of what they learnt about computers in the comfort of their own home. We want to give you that same opportunity, to experience the joy of learning how to use computers to solve all sorts of problems: writing a letter to a friend, working out how much tax you owe, inventing new things, or discovering how the universe works. This is why we made the **MEGA65**.

The MEGA65 team thinks that owning a computer should be like owning a home: You don't just use a home, you change things big and small to really make it your own, and maybe even renovate it or add on a room or two. In this guide we will show you how to more than just hang your own pictures on the wall, but instead how you can dream up new ways of using the powerful capabilities of computers by coding your own computer programmes, and even changing the computer itself!

To help you have fun with your MEGA65, we will show you how to use the exciting **graphics** and **sound** capabilities of the MEGA65. But the MEGA65 isn't just about writing your own programmes. It can also run many of the thousands of games and other programmes that were created for the Commodore® 64^{TM2} computer.

Welcome to the world of the **MEGA65**!

¹ Commodore is a trademark of C= Holdings

² Commodore 64 is a trademark of C= Holdings,

**GETTING TO KNOW YOUR
MEGA65**

CHAPTER 2

SETUP

- **Unpacking and connecting the MEGA65**
- **Rear Connections**
- **Side Connections**
- **Installation**
- **Optional Connections**
- **Operation**

UNPACKING AND CONNECTING THE MEGA65

Time to set up your MEGA65 home computer. The box contains the following:

- MEGA65 computer.
- Power supply (black box with socket for mains supply).
- This book, the MEGA65 User's Guide.

In addition, to be able to use your MEGA65 computer:

- A television or computer monitor with a VGA or digital video input, that is capable of displaying an image with 800x600 pixel resolution at 50Hz or 60Hz.
- A VGA video cable, or;
- A digital video cable.

These items are not included with the MEGA65.

You may also want to use the following to get the most out of your MEGA65:

- 3.5mm mini-jack audio cable and suitable speakers or hifi system, so that you can enjoy the sound capabilities of your MEGA65.
- RJ45 ethernet cable (regular network cable) and a network router or switch. This allows use of the high-speed networking capabilities of your MEGA65.

REAR CONNECTIONS

- | | |
|---|----------------------------|
| 1 | 3.5mm Audio Mini-Jack |
| 2 | SDCard |
| 3 | Network LAN Port |
| 4 | Digital Video Connector |
| 5 | VGA Video Connector |
| 6 | External Floppy Disk Drive |
| 7 | Cartridge Expansion Port |
| 8 | DC Power-In Socket |

SIDE CONNECTIONS

- | | |
|---|-------------------|
| 1 | Power Switch |
| 2 | Controller Port 2 |
| 3 | Controller Port 1 |
| 4 | Reset Button |

Various peripherals can be connected to Controller Ports 1 and 2 such as joysticks or paddles.

INSTALLATION

Connecting your MEGA65 to a screen and peripherals

1. Connect the power supply to the Power Supply socket of the MEGA65.
2. If you have a VGA monitor and a VGA cable, connect one end to the VGA port of the MEGA65 and the other end into your VGA monitor.
3. If you have a TV or monitor with a Digital Video connector, connect one end of your cable to the Digital Video port of the MEGA65, and the other into the Digital Video port of your monitor. If you own a monitor with a DVI socket, you can purchase a DVI to Digital Video adapter.

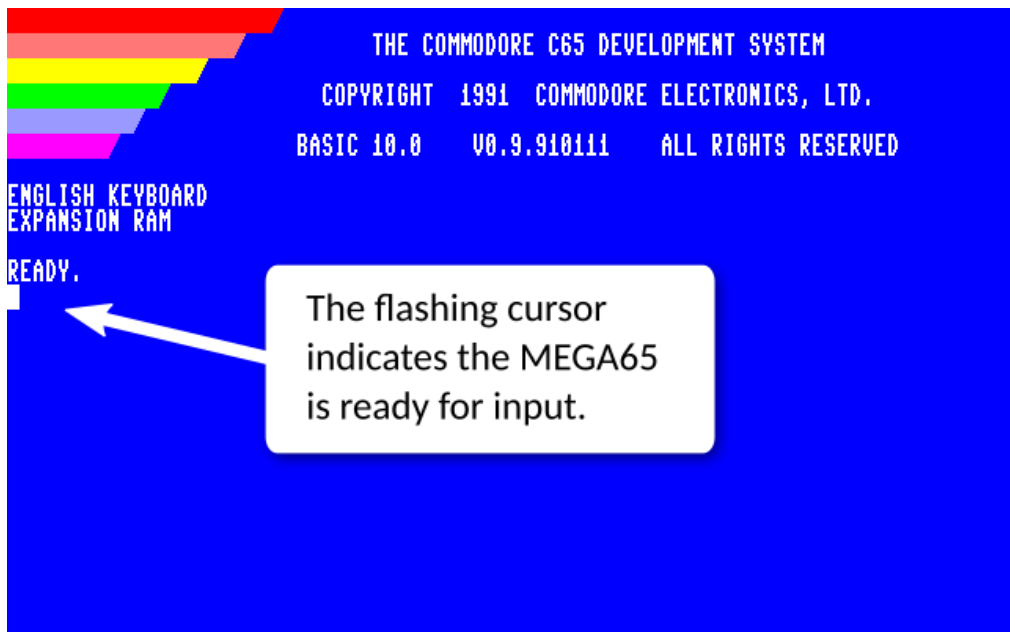

OPTIONAL CONNECTIONS

1. The MEGA65 houses an internal 3.5" floppy disk drive. You can also connect older Commodore® IEC serial floppy drives to the MEGA65: the Commodore® 1541, 1571 or 1581. Connect one end of your IEC cable to the Commodore® floppy disk drive and the other end to the Disk Drive socket of the MEGA65. You can also connect SD2IEC devices and PI1541's. It is possible to daisy-chain additional floppy disk drives or Commodore® compatible printers.
2. You can connect your MEGA65 to a network using a standard ethernet cable.
3. For enjoying audio from your MEGA65, you can connect a 3.5mm stereo mini-jack cable to an audio amplifier or speaker system. If your system has RCA connectors you will need to purchase a 3.5mm mini-jack to twin RCA adapter cable. The MEGA65 also has a built in amplifier to allow connecting headphones.
4. A Secure Digital Card or SDCard (SDHC and SDXC) can be inserted into the rear of the MEGA65 as a drive.

OPERATION

Using the MEGA65

1. Turn on the computer by using the switch on the left hand side of the MEGA65.
2. After a moment, the following will be displayed on your TV or monitor:

THE CURSOR

The flashing square underneath the READY prompt is called the cursor. The cursor indicates that the computer is ready to accept input. Pressing keys on the keyboard will print that character onto the screen. The character will be printed in the current cursor position, and then the cursor advances to the next position.

You can type commands, for example: telling the computer to load a program. You can even start entering program code.

CHAPTER 3

GETTING STARTED

- **Keyboard**
- **The Screen Editor**
- **Editor Functionality**

KEYBOARD

Now that you have everything connected, it's time to get familiar with the MEGA65 keyboard.

You may notice that the keyboard is a little different from the standard used on computers today. While most keys will be in familiar positions, there are some specialised keys, and some with special graphic symbols marked on the front.

Here's a brief description of how some of these special keys function.

Command Keys

The Command Keys are: **RETURN**, **SHIFT**, **CTRL**, **M** and **RESTORE**.

RETURN

Pressing the **RETURN** key enters the information you have typed into the MEGA65's memory. The computer will either act on a command, store some information, or return you an error if you made a mistake.

SHIFT

The two **SHIFT** keys are located on the left and the right. They work very much like Shift on a regular keyboard, however they also perform some special functions too.

In upper case mode, holding **SHIFT** and pressing any key with a graphic symbol on the front produces the right hand symbol on that key. For example, **SHIFT** and **J** prints the ☐ character.

In lower case mode, pressing **SHIFT** and a letter key prints the upper case letter on that key.

Holding both shift keys down when turning the machine on activates the Utility Menu. You can format the SD card or enter the MEGA65 Configuration Utility to select the default video mode and other settings.

Finally, holding the **SHIFT** key and pressing a Function key accesses the function shown on the front of that key. For example: **SHIFT** and **F1** activates **F2**.

SHIFT LOCK

In addition to the Shift key is . Press this key to lock down the Shift function. Now any key you press prints the character to the screen as if you were holding down Shift. That includes special graphic characters.

CTRL

CTRL is the Control key. Holding down Control and pressing another key allows you to perform Control Functions. For example, holding  and one of the number keys allows you to change text colours.

There are some examples of this in the Screen Editor chapter, and all the Control Functions are listed in Appendix C Control codes.

If a program is being listed to the screen, holding  slows down the display of each line on the screen.

Holding  and pressing  enters the Matrix Mode Debugger.

RUN/STOP

Normally, pressing the  key stops execution of a program. Holding  while pressing  loads the first program from disk.

Programs are able to disable the  key.

You can boot your machine into the machine code monitor by holding down  and pressing reset on the MEGA65.

RESTORE

The computer screen can be restored to a clean state without clearing the memory by holding down the  key and tapping .

Programs are able to disable this key combination.

Enter the Freeze Menu by holding  for more than one second. You can access the machine code monitor via the Freeze menu.

THE CURSOR KEYS

At the bottom right hand of the keyboard are the cursor keys. These four directional keys allow you move the cursor to any position for onscreen editing.

The cursor moves in the direction indicated on the keys:    

However, it is also possible to move the cursor up using  and . In the same way you can move the cursor left using  and .

You don't have to keep pressing a cursor key over and over. When moving the cursor a long way, you can keep the key pressed in. When you are finished, release the key.

INSerT/DELeTe

This is the INSERT / DELETE key. When pressing , the character to the left is deleted, and all characters to the right are shifted one position to the left.

To insert a character, hold the  key and press . All the characters are shifted to the right. This allows you to type a letter, number or any other character into the newly inserted space.

CLear/HOME

Pressing the  key returns the cursor into the top left-most position of the screen.

If holding  and pressing  clears the entire screen and places the cursor into the top left-most position of the screen.

MEGA KEY

The  key or the MEGA key provides a number of different functions and special utilities.

Holding the  key and pressing  switches between lower and upper case character modes.

Holding  and pressing any key with graphic symbols on the front prints the left-most graphic symbol to the screen.

Holding  and pressing any key that shows a single graphic symbol on the front prints that graphic symbol to the screen.

Holding  and pressing a number key switches to one of the colours in the second range.

Holding  and pressing  enters the Matrix Mode Debugger.

When turning on the MEGA65 or pressing the reset button on the side, while holding  switches the MEGA65 into C64 mode.

NO SCROLL

If a program is being listed to the screen, pressing  freezes the screen output. Not available in C64 mode.

Function Keys

There are seven Function keys available for use by software applications,       and  to perform functions with a single press.

Hold  to access  through to  as shown on the front of each Function key.

Only Function keys  to  are available in C64 mode.

HELP

The  key can be used by software and acts as an  /  key.

ALT

The  held while pressing other keys can be used by software to perform functions. Not available in C64 mode.

CAPS LOCK

The  works like  in C65 and MEGA65 modes, but only modifies the alphabet keys. Also, holding the  down forces the processor to run at the maximum speed. This can be used, for example, to speed up loading from the internal disk drive or SD card, or to greatly speed up the depacking process after a program is run. This can reduce the loading and depacking time from many seconds to as little as a 10th of a second.

THE SCREEN EDITOR

When you turn on your MEGA65, or reset it, the editor screen will appear.

The colour bars in the top left hand of the screen can be used as a guide to help calibrate the colours of your display. The screen also displays the name of the system, the copyright notice and what version and revision of BASIC is contained in the Read-only Memory.

Also displayed is the type of keyboard and whether or not there is additional hardware present, such as a RAM expansion.

Finally, you will see the READY prompt and the flashing cursor.

You can begin typing keys on the keyboard and the characters will be printed under the cursor. The cursor itself advances after each key press.

You can also produce reverse text or colour bars by holding down the **CTRL** key and pressing the **9** key or the **R** key. This enters reverse text mode.

Try holding down the **SPACE BAR**. A white bar will be drawn across the screen.

You can even change the current colour by holding down the **CTRL** key and pressing a number key. Try key **8** and then hold down the **SPACE BAR** again. A yellow bar will be drawn.

Change the bar to a number of other colours.

You will get an effect something like:

You can turn off the reverse text mode by holding **CTRL** and pressing the **0** key.

By pressing any keys, the characters will be typed out in the chosen colour.

There are a further eight colours available via the **M** key. Hold the **M** key and press a key from **1** to **8** to change to one of the secondary colours. For even more colours, see Escape Sequences in Appendix C.

Functions

Functions using the **CTRL** key are called **Control Functions**. Functions using the **M** key are called **Mega Functions**. There are also functions called by using the **SHIFT** key. These are (not surprisingly) called **Shift Functions**.

Lastly, using the **ESC** key are **Escape Sequences**.

ESC Sequences

Escape sequences are performed a little differently than a Control function or a Shifted function. Instead of holding the modifier key down, an Escape sequence is performed by pressing the **ESC** key once, then pressing the desired key code.

For example: to switch between 40/80 column mode, press and release the **ESC** key. Then press the **X** key.

You can see all the available Escape Sequences in Appendix C. We will cover some examples of these shortly.

There are more modes available. You can create flashing text by holding the **CTRL** key and pressing the **O** key. Any characters you press will flash. Turn flash mode off by pressing **ESC** then **O**.

EDITOR FUNCTIONALITY

The MEGA65 screen can allow you to do advanced tabbing, and moving quickly around the screen in many ways to help you to be more productive.

Press the **HOME** key to go to the home position on the screen. Hold the **CTRL** key down and press the **W** key several times. This is the **Word Advance function** which jumps your cursor to the next word, or printable character.

You can set custom tab positions on the screen for your convenience. Press **HOME** and then **→** to the fourth column. Hold down **CTRL** and press the **X** key to set a tab. Move another 20 positions to the right again, and do **CTRL** and **X** again to set a second tab.

Press the **HOME** key to go back to the home position. Hold the **CTRL** key and press the **I** key. This is the **Forward Tab function**. Your cursor will tab to the fourth position. Press **CTRL** and **I** again. Your cursor will move to position 8. Why? By default, every 8th position is already set as a tabbed position. So the 4th and 20th positions have been added to the existing tab positions. You can continue to press the **CTRL** and **I** keys to the 16th and 20th positions.

To find the complete set of Control codes, see Appendix C Control codes.

Creating a Window

You can set a window on the MEGA65 working screen. Move your cursor to the beginning of the "BASIC 10.0" text. Press **ESC**, then press **T**. Move the cursor 10 lines down and 15 to the right.

Press the **ESC** key, then **B**. Anything you type will be contained within this window.

To escape from the window back to the full screen, press the **HOME** key twice.

Extras

Long press on **RESTORE** to go into the Freeze Menu. Then press **J** to switch joystick ports without having to physically swap the joystick to the other port.

Go to **Fast mode** with poke 0, 65 or go to the freeze menu.

MEGA and **SHIFT** switches between text uppercase and lowercase for the entire display.

PART II

FIRST STEPS IN CODING

CHAPTER 4

How Computers Work

- **Computers are just a pile of switches**

Computers can do amazing things, and you can make them do amazing things for you, too. But to do that, you need to understand how computers work. This can be hard to find out these days, because computers are now so complicated that it isn't obvious just by looking at them and using them. The MEGA65 is designed to be simple enough that you can learn how computers work as you use it. But we don't want to leave you to have to work out everything for yourself. This chapter will help you to understand how computers work, and then use that knowledge to help you make computers do what *you* want them to do.

COMPUTERS ARE JUST A PILE OF SWITCHES

What are computers *really*? Well, the answer to that question is quite simple, if a little surprising: Computers really are just made of lots of switches. These switches work like the switches you use to turn a light on or off. Light switches connect or disconnect the power supply to a light. The switches in computers connect or disconnect circuits in the computer to power. But computers can do a lot more than just switch on and off, so something else must be going on. That something else is also a bit of a surprise: A computer can turn its own switches on and off by itself. Let's explore how this simple idea of switches that can turn themselves on and off makes a computer.

Computers are full of switches. When you hear people talking about microns and nanometres with regard to computers, they are often talking about the size of the little switches that make up the computer chips. These switches are called transistors. The switches in the main chip of the MEGA65, for example, are 28 nanometres long. That's about 100,000 times thinner than a single strand of hair. This is good, because a computer might need millions or billions of switches in its design.

HARDWARE

CHAPTER 5

Using a Nexys4DDR as a MEGA65

- Building your own MEGA65 Com-
patible Computer
- Power, Jumpers, Switches and Buttons
- Keyboard
- Preparing microSDHC card
- Useful Tips

BUILDING YOUR OWN MEGA65 COMPATIBLE COMPUTER

You can build your own MEGA65-compatible computer by using a Nexys4DDR FPGA development board. This appendix describes the process to setup a Nexys4DDR board for this purpose. The older non-DDR Nexys4 board is also supported, and the instructions are the same, except that you must use a bitstream designed for that board. Using a Nexys4DDR bitstream on a non-DDR Nexys4 board, or vice versa, may cause irreparable damage to your board, so make sure you have the correct bitstream to suit your board.

DISCLAIMER: M.E.G.A cannot take any responsibility for any damage that may occur to your Nexys4DDR board.

POWER, JUMPERS, SWITCHES AND BUTTONS

The MEGA65 core consumes too much power for the Nexys4DDR board to be powered from a standard USB port. In particular, writing to the SD card might hang or perform odd behaviour. Therefore you should use a 5V power supply. Digilent sell a power supply for the Nexys4DDR board, and we recommend you use this to ensure you avoid the risk of damage to your Nexys4DDR board.

Set the following jumpers on your Nexys4DDR board to the following positions:

- JP1 – USB/SD
- JP2 – SD
- JP3 – Wall

All 16 switches on the lower edge of the board must be set to the off position.

The “CPU RESET” button will reset the MEGA65 when pressed, while the “PROG” button will cause the FPGA itself to reload the MEGA65 core. The main difference between the two is that CPU RESET is faster, and does not clear the contents of memory, while the FPGA button is slower, and does reset the contents of memory.

Two of the five buttons in the cross arrangement can also be used: BTNU acts as though you have pressed the **RESTORE** key, while BTNC will trigger an IRQ, as though the IRQ line had been pulled to ground.

KEYBOARD

Only USB keyboards that lack a USB hub will work with the Nexys4DDR board. Generally extremely cheap keyboards will work, while more expensive keyboards tend to have a USB hub integrated, and will not work. You may need to try several keyboards, before you find one that works.

The keyboard layout is positional rather than logical. This means that keys in similar positions to the keys on a C65 keyboard will have similar function. This relationship assumes that your USB keyboard uses a US keyboard layout.

The **RESTORE** key is mapped to the PAGE UP key.

PREPARING MICROSDHC CARD

The MEGA65 requires an SDHC card of between 4GB and 64GB capacity. Some SDXC cards may work, however, this is not officially supported.

To prepare your SD card, you will need the following two separate files from the MEGA65 web site:

- Bitstream <http://mega65.org/assets/bitstream.7z>
- Support Files <http://mega65.org/assets/fileset.7z>

In addition, you will also need a C65 ROM. There were many different versions created during the development of the Commodore 65, and the MEGA65 can use any of them. However, we recommend you use 911001.bin, as this has the most complete BASIC and DOS implementations.

The steps are:

- Format the SD card in a convenient computer using the FAT32 filesystem. The MEGA65 and Nexys4DDR boards do not understand other file systems, especially the exFAT file system.
- Unzip the bitstream.7z file, and copy the file with name ending in “.bit” onto the SD card.
- Insert the SD card into the SD card slot on the under-side of the Nexys4DDR board.
- Turn on the Nexys4DDR board.
- Enter the Utility Menu by holding the left and right SHIFT keys down on the USB keyboard you have connected to the Nexys4DDR board.
- Enter the FDISK/FORMAT tool by pressing 2 when the option appears on the MEGA65 boot screen.
- Follow the prompts in the FDISK/FORMAT program to again format the SD card for use by the MEGA65. (The FDISK tool will partition your SD card into two partitions and format them. One is type \$41 = MEGA65 System Partition, where the save slots, configuration data and other files live. (This partition is invisible in i.e. Win PCs). and the other partition with type \$0C = VFAT32, where KERNEL, support files, games, and so on, will be copied to later. (This partition is visible on i.e. Win PCs).
- Once formatting is complete, switch off the Nexys4DDR board and remove the microSDHC card from the Nexys board and put it back into your PC
- Again copy the bitstream back onto the SD card, as well as all the files from the other 7z file downloaded from the MEGA65 website.

- Copy the 911001.bin ROM file onto the SD card, and rename it to MEGA65.ROM
- If you have any .D81 files, copy them onto the SD card. Make sure that they have names that fit the old DOS 8.3 character limit, and are upper case. This restriction will be removed in a future release.
- Remove the SD card and reinsert it into your Nexys4DDR board.
- Power the Nexys4DDR board back on. The MEGA65 should boot within 15 seconds.

Congratulations. Your MEGA65 has been set up and is ready to use.

USEFUL TIPS

The following are some useful tips for getting familiar with the MEGA65:

- Press & hold  (or the Commodore key if using a Commodore 64 or 65 keyboard) during boot to start up in C64 mode instead of C65 mode
- Press & hold  during boot to enter the machine language monitor, instead of starting BASIC.
- Press the **RESTORE** key for approximately 1/2 - 1 second to enter the MEGA65 Freeze Menu. From this menu you have convenient tools to change the CPU speed, switch between PAL & NTSC video mode, change Audio settings, manage freeze-states, select D81 disk images, examine and modify memory of the frozen program, among other features. This is in many ways the heart of the MEGA65, so it is well worth exploring and getting familiar with.
- Press the **RESTORE** for about 2 seconds to reset the MEGA65. This is a temporary feature that will be removed when the MEGA65 desktop computers with built-in reset button become available.
- Type **POKE0,65** in C64 mode to switch the CPU to full speed (40MHz). Some software may behave incorrectly in this mode, while other software will work very well, and run many times faster than on a C64.
- Type **POKE0,64** in C64 mode to switch the CPU to 1MHz.
- Type **\$V\$58552** in C64 mode to switch to C65 mode.
- Type **6064** in C65 mode and confirm, by pressing **Y**, to switch to C64 mode, just like on a C128.

- The C65 ROM makes device 8 the default, so you can normally leave off the ,8 from the end of LOAD and SAVE commands.
- Pressing **SHIFT** + **RUN STOP** from either C64 or C65 mode will attempt to boot from disk.

Have fun! The MEGA65 has been lovingly crafted over many years for your enjoyment. We hope you have as much fun using it as we have had creating it!

The MEGA Museum of Electronic Games and Art welcomes your feedback, suggestions and contributions to this open-source digital heritage preservation project.

PART V

APPENDICES

APPENDICES

APPENDIX A

ACCESSORIES

APPENDIX

B

BASIC 10 Command Reference

- **Format of Commands, Functions
and Operators**
- **Commands, Functions and Operators**

FORMAT OF COMMANDS, FUNCTIONS AND OPERATORS

This appendix describes each of the commands, functions and other callable elements of BASIC 10. Some of these can take one or more arguments, that is, pieces of input that you provide as part of the command or function call. Some also require that you use special keywords. Here is an example of how commands, functions and operators will be described in this appendix:

KEY <numeric expression>,<string expression>

In this case, KEY is what we call a **keyword**. That just means a special word that BASIC understands. Keywords are always written in CAPITALS, so that you can easily recognise them.

The < and > signs mean that whatever is between them must be there for the command, function or operator to work. In this case, it tells us that we need to have a **numeric expression** in one place, and a **string expression** in another place. We'll explain what there are a bit more in a few moments.

You might also see square brackets around something, for example, [**numeric expression**]. This means that whatever appears between the square brackets is optional, that is, you can include it if you need to, but that the command, function or operator will work just fine without it. For example, the **CIRCLE** command has an optional numeric argument to indicate if the circle should be filled when being drawn.

The comma, and some other symbols and punctuation marks just represent themselves. In this case, it means that there must be a comma between the **numeric expression** and the **string expression**. This is what we call syntax: If you miss something out, or put the wrong thing in the wrong place, it is called a syntax error, and the computer will tell you if you have a syntax error by giving a **?SYNTAX ERROR** message.

There is nothing to worry about getting an error from the computer. Instead, it is just the computer's way of telling you that something isn't quite right, so that you can more easily find and fix the problem. Error messages like this can't hurt the computer or damage your program, so there is nothing to worry about. For example, if we accidentally left the comma out, or replaced it with a full-stop, the computer will respond with a syntax error, like this:

```
KEY 8"FISH"
```

```
?SYNTAX ERROR
```

```
KEY 8."FISH"
```

```
?SYNTAX ERROR
```

It is very common for commands, functions and operators to use one or more **"expression"**. An expression is just a fancy name for something that has a value. This could be a string, such as `"HELLO"`, or a number, like `23.7`, or it could be a calculation, that might include one or more functions or operators, such as `LEN("HELLO") * (3 XOR 7)`. Generally speaking, expressions can result in either a string or numeric result. In this case we call the expressions either string expressions or numeric expressions. For example, `"HELLO"` is a **string expression**, while `23.7` is a **numeric expression**.

It is important to use the correct type of expression when writing your programs. If you accidentally use the wrong type, the computer will give you a `?TYPE MISMATCH ERROR`, to say that the type of expression you gave doesn't match what it expected, that is, there is a mismatch between the type of expression it expected, and the one you gave. For example, we will get a `?TYPE MISMATCH ERROR` if we type the following command, because `"POTATO"` is a string expression instead of a numeric expression:

```
KEY "POTATO","SOUP"
```

You can try typing this into the computer yourself now, if you like.

COMMANDS, FUNCTIONS AND OPERATORS

Commands are statements that you can use directly from the **READY.** prompt, or from within a program, for example:

```
PRINT "HELLO"
```

```
HELLO
```

```
10 PRINT "HELLO"
```

```
RUN
```

HELLO

ABS

Token: \$B6

Format: **ABS(x)**

Usage: The numeric function **ABS(x)** returns the absolute value of the numeric argument **x**.
x = numeric argument (integer or real expression).

Remarks: The result is of real type.

Example: Using **ABS**

```
PRINT ABS(-123)
123
PRINT ABS(4.5)
4.5
PRINT ABS(-4.5)
4.5
```

AND

Token: \$AF

Format: operand **AND** operand

Usage: The boolean **AND** operator performs a bitwise logical AND operation on two 16-bit values. Integer operands are used as they are. Real operands are converted to a signed 16 bit integer. Logical operands are converted to 16 bit integer using \$FFFF, decimal -1 for TRUE and \$0000, decimal 0, for FALSE.

```
0 AND 0 -> 0
0 AND 1 -> 0
1 AND 0 -> 0
1 AND 1 -> 1
```

Remarks: The result is of integer type. If the result is used in a logical context, the value of 0 is regarded as FALSE, all other, nonzero values are regarded as TRUE.

Example: Using **AND**

```
PRINT 1 AND 3
1
PRINT 128 AND 64
0
```

In most cases the **AND** will be used in **IF** statements.

```
IF (C >= 0 AND C < 256) THEN PRINT "BYTE VALUE"
```

APPEND

Token: \$FE \$OE

Format: **APPEND# lfn, filename [,D drive] [,U unit]**

Usage: Opens an existing sequential file of type SEQ or USR for writing and positions the write pointer at the end of the file.

lfn = logical file number

1 <= lfn <= 127: line terminator is CR

128 <= lfn <= 255: line terminator is CR LF

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: **APPEND#** functions similar to the **DOPE#** command, except that if the file already exists, the existing content of the file will be retained, and any **PRINT#** commands made to the open file will cause the file to grow longer.

Example: Open file in append mode:

```
APPEND#5,"DATA",U9
APPEND#130,(DD$),U(UN%)
APPEND#3,"USER FILE,U"
APPEND#2,"DATA BASE"
```

ASC

Token: \$C6

Format: **ASC**(string)

Usage: Takes the first character of the string argument and returns its numeric code value. The name is apparently chosen to be a mnemonic to ASCII, but the returned value is in fact the so called PETSCII code.

Remarks: **ASC** returns a zero for an empty string, which behaviour is different to BASIC 2, where `ASC("")` gave an error. The inverse function to **ASC** is **CHR\$**.

Example: Using **ASC**

```
PRINT ASC("MEGA")
77
PRINT ASC("")
0
```

ATN

Token: \$C1

Format: **ATN**(numeric expression)

Usage: Returns the arc tangent of the argument. The result is in the range $(-\pi/2$ to $\pi/2)$

Remarks: A multiplication of the result with $180/\pi$ converts the value to the unit "degrees". **ATN** is the inverse function to **TAN**.

Example: Using **ATN**

```
PRINT ATN(0.5)
.463647609
PRINT ATN(0.5) * 180 / π
26.5650512
```

AUTO

Token: \$DC

Format: **AUTO [step]**

Usage: Enables faster typing of BASIC programs. After submitting a new program line to the BASIC editor with the RETURN key, the AUTO function generates a new BASIC line number for the entry of the next line. The new number is computed by adding **step** to the current line number.

step = line number increment

Typing **AUTO** with no argument switches this function off.

Example: **AUTO 10** - use AUTO with increment 10
AUTO - switch AUTO off

BACKGROUND

Token: \$FE \$3B

Format: **BACKGROUND** colour

Usage: Sets the background colour of the screen to the argument, which must be in the range 1 to 16. (See colour table).

Example: **BACKGROUND 4** - select background colour cyan.

Colours: **Index and RGB values of colour palette**

index	red	green	blue	colour
1	0	0	0	black
2	15	15	15	white
3	15	0	0	red
4	0	15	15	cyan
5	15	0	15	magenta
6	0	15	0	green
7	0	0	15	blue
8	15	15	0	yellow
9	15	6	0	orange
10	10	4	0	brown
11	15	7	7	pink
12	5	5	5	dark grey
13	8	8	8	medium grey
14	9	15	9	light green
15	9	9	15	light blue
16	11	11	11	light grey

BACKUP

Token: \$F6

Format: **BACKUP D source TO D target [,U unit]**

Usage: Used on dual drive disk units only (e.g. 4040, 8050, 8250). The backup is done by the disk unit internally.

source = drive # of source disk (0 or 1).

target = drive # of target disk (0 or 1).

Remarks: The target disk is formatted and a identical copy of the source disk is written.

This command cannot be used for unit to unit copies.

Example: **BACKUP D0 TO D1** – copy disk in drive 0 to drive 1 on unit 8 (default).
BACKUP D1 TO D0, U9 – copy disk in drive 1 to drive 0 on unit 9.

BANK

Token: \$FE \$02

Format: **BANK** banknumber

Usage: Selects the memory configuration for BASIC commands, that use 16-bit addresses. These are LOAD, SAVE, PEEK, POKE, WAIT and SYS. See system memory map for details.

Remarks: A value > 127 selects memory mapped I/O. The default value for the bank number is 128.

Example: **BANK 1** - select memory configuration 1.

BEGIN

Token: \$FE \$18

Format: **BEGIN ... BEND**

Usage: The **BEGIN** and **BEND** keywords act like a pair of brackets around a compound statement to be executed after a **THEN** or **ELSE** keyword. This overcomes the single line limitation of the standard **IF ... THEN ... ELSE** clause.

Remarks: Do not jump with **GOTO** or **GOSUB** into a compound statement. It may lead to unexpected results.

Example: Using **BEGIN** and **BEND**

```
10 GET A$
20 IF A$>="A" AND A$<="Z" THEN BEGIN
30 PW$=PW$+A$
40 IF LEN(PW$)>7 THEN 90
50 BEND :REM IGNORE ALL EXCEPT (A-Z)
60 IF A$<>CHR$(13) GOTO 10
90 PRINT "PW=";PW$
```

BEND

Token: \$FE \$19

Format: **BEGIN ... BEND**

Usage: The **BEGIN** and **BEND** keywords act like a pair of brackets around a compound statement to be executed after a **THEN** or **ELSE** keyword. This overcomes the single line limitation of the standard **IF ... THEN ... ELSE** clause.

Remarks: The example below shows a quirk in the implementation of the compound statement. If the condition evaluates to **FALSE**, execution does not resume right after **BEND** as it should, but at the beginning of next line. Test this behaviour with the following program:

Example: Using **BEGIN** and **BEND**

```
10 IF Z > 1 THEN BEGIN:A$="ONE"
20 B$="TWO"
30 PRINT A$;" ";B$;;BEND:PRINT " QUIRK"
40 REM EXECUTION RESUMES HERE FOR Z <= 1
```

BLOAD

Token: \$FE \$11

Format: **BLOAD** filename [,B bank] [,P address] [,D drive] [,U unit]

Usage: "Binary LOAD" loads a file of type PRG into RAM at address P and bank B.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

bank specifies the RAM bank to be used. If not specified the current bank, as set with the last **BANK** statement, will be used.

address can be used to overrule the load address, that is stored in the first two bytes of the PRG file.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: If the loading process tries to load beyond the address \$FFFF, an 'OUT OF MEMORY' error occurs.

Example: Using **BLOAD**

```
BLOAD "ML DATA", B0, U9
BLOAD "SPRITES"
BLOAD "ML ROUTINES", B1, P32768
BLOAD (FN$), B(BA%), P(PA), U(UN%)
```

BOOT

Token: \$FE \$1B

Format: **BOOT filename** [,B bank] [,P address] [,D drive] [,U unit]
BOOT SYS
BOOT

Usage: **BOOT filename** loads a file of type PRG into RAM at address P and bank B and starts executing the code at the load address.

BOOT SYS loads the boot sector from sector 0, track 1 and unit 8 to address \$0400 on bank 0 and performs a JSR \$0400 afterwards (Jump To Subroutine).

The **BOOT** command with no parameter tries to load and execute a file named AUTOBOOT.C65 from the default unit 8. It's short for **RUN "AUTOBOOT.C65"**.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

bank specifies the RAM bank to be used. If not specified the current bank, as set with the last **BANK** statement, will be used.

address can be used to overrule the load address, that is stored in the first two bytes of the PRG file.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: **BOOT SYS** copies the contents of one physical sector (two logical sectors) = 512 bytes from disc to RAM, filling RAM from \$0400 to \$05ff.

Example: Using **BOOT**

```
BOOT SYS
BOOT (FN$), B(BA%), P(PA), U(UN%)
BOOT
```

BORDER

- Token:** \$FE \$3C
- Format:** **BORDER** colour
- Usage:** Sets the border colour of the screen to the argument, which must be in the range 1 to 16. (See colour table).
- Example:** **BORDER 5** - select background colour magenta.
- Colours:** **Index and RGB values of colour palette**

index	red	green	blue	colour
1	0	0	0	black
2	15	15	15	white
3	15	0	0	red
4	0	15	15	cyan
5	15	0	15	magenta
6	0	15	0	green
7	0	0	15	blue
8	15	15	0	yellow
9	15	6	0	orange
10	10	4	0	brown
11	15	7	7	pink
12	5	5	5	dark grey
13	8	8	8	medium grey
14	9	15	9	light green
15	9	9	15	light blue
16	11	11	11	light grey

BOX

Token: \$E1

Format: **BOX X0,Y0, X1,Y1, X2,Y2, X3,Y3, SOLID**

Usage: Draws a quadrangle by connecting the coordinate pairs 0 -> 1 -> 2 -> 3 -> 0. The quadrangle is drawn using the current drawing context set with SCREEN, PALETTE and PEN. The quadrangle is filled, if the parameter SOLID is 1.

Remarks: A quadrangle is a geometric figure with four sides and four angles. A box is a special form of a quadrangle, with all four angles at 90 degrees. Rhomboids, kites and parallelograms are special forms too. So the name of this command is misleading, because it can be used to draw all kind of quadrangles, not only boxes. It is possible to draw bowtie shapes.

Example: Using **BOX**

```
BOX 0,0, 160,0, 160,80, 0,80
```

```
BOX 0,0, 160,80, 160,0, 0,80
```

```
BOX 0,0, 160,0, 140,80, 20,80
```

BSAVE

Token: \$FE \$10

Format: **BSAVE** filename ,P start TO end [,B bank] [,D drive] [,U unit]

Usage: "Binary SAVE" saves a memory range to a file of type PRG.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)** If the first character of the filename is an at-sign '@' it is interpreted as a "save and replace" operation. It is dangerous to use this replace option on drives 1541 and 1571, because they contain the notorious "save and replace bug" in their DOS.

bank specifies the RAM bank to be used. If not specified the current bank, as set with the last **BANK** statement, will be used.

start is the first address, where the saving begins. It becomes also the load address, that is stored in the first two bytes of the PRG file.

end is the address, where the saving stops. **end-1** is the last address to be used for saving.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The length of the file is **end - start + 2**.

Example: Using **BSAVE**

```
BSAVE "ML DATA", P 32768 TO 33792, B0, U9
BSAVE "SPRITES", P 1536 TO 2058
BSAVE "ML ROUTINES", B1, P(DEC("9000")) TO (DEC("A000"))
BSAVE (FN$), B(BA%), P(PA) TO (PE), U(UN%)
```

BUMP

Token: \$CE \$03

Format: **b** = BUMP(type)

Usage: Used to detect sprite-sprite (type=1) or sprite-data (type=2) collisions. the return value **b** is a 8-bit mask with one bit per sprite. The bit position corresponds with the sprite number. Each bit set in the return value indicates, that the sprite for this position was involved in a collision since the last call of **BUMP**. Calling **BUMP** resets the collision mask, so you get always a summary of collisions encountered since the last call of **BUMP**.

Remarks: It's possible to detect multiple collisions, but you need to evaluate sprite coordinates then to detect which sprite collided with which one.

Example: Using **BUMP**

```
$% = BUMP(1) : REM SPRITE-SPRITE COLLISION
IF ($% AND 6) = 6) THEN PRINT "SPRITE 1 & 2 COLLISION"

$% = BUMP(2) : REM SPRITE-DATA COLLISION
IF ($% <> 0) THEN PRINT "SOME SPRITE HIT DATA REGION"
```

sprite	return	mask
0	1	0000 0001
1	2	0000 0010
2	4	0000 0100
3	8	0000 1000
4	16	0001 0000
5	32	0010 0000
6	64	0100 0000
7	128	1000 0000

BVERIFY

Token: \$FE \$28

Format: **BVERIFY** filename [,P address] [,B bank] [,D drive] [,U unit]

Usage: "Binary VERIFY" compares a memory range to a file of type PRG.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

bank specifies the RAM bank to be used. If not specified the current bank, as set with the last **BANK** statement, will be used.

address is the address, where the comparison begins. If the parameter P is omitted, it is the load address, that is stored in the first two bytes of the PRG file.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: **BVERIFY** can only test for equality. It gives no information about the number or position of different valued bytes. In direct mode the command exits either with the message **OK** or with **VERIFY ERROR**. In program mode a **VERIFY ERROR** either stops execution or enters the **TRAP** error handler, if active.

Example: Using **BVERIFY**

```
BVERIFY "ML DATA", P 32768, B0, U9
BVERIFY "SPRITES", P 1536
BVERIFY "ML ROUTINES", B1, P(DEC("9000"))
BVERIFY (FN$), B(BA%), P(PA), U(UN%)
```

CATALOG

Token: \$FE \$0C

Format: **CATALOG** [**filepattern**] [**R**] [**D drive**] [**U unit**]

Usage: Prints a listing of the specified disk.

The **R** (Recoverable) parameter includes files in the directory, which are flagged as deleted but are still recoverable.

filepattern is either a quoted string, for example: "**da***" or a string expression in parentheses, e.g. (**DI\$**)

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The command **CATALOG** is a synonym for **DIRECTORY** or **DIR** and produces the same listing. The **filepattern** can be used to restrict the listing. The wildcard characters ***** and **?** may be used. Adding a **,T=** to the pattern string, with T specifying a filetype P,S,U or R (for PRG,SEQ,USR,REL) restricts the output to that filetype.

Example: Using **CATALOG**

```
CATALOG
 0 "BLACK SMURF"    " BS  2A
508 "STORY PHOBOS"      SEQ
27  "C8096"          PRG
25  "C128"           PRG
104 BLOCKS FREE.

DIRECTORY "*,T=S"
 0 "BLACK SMURF"    " BS  2A
508 "STORY PHOBOS"      SEQ
104 BLOCKS FREE.
```

CHANGE

Token: \$FE \$0C

Format: **CHANGE "find" TO "replace" [,from-to]**

Usage: Used in direct mode only. It searches the line range if specified or the whole BASIC program else. At each occurrence of the "find string" the line is listed and the user prompted for an action:
'Y' <RETURN> do the change and find next string
'N' <RETURN> do **not** change and find next string
'*' <RETURN> change this and all following matches
<RETURN> exit command, don't change.

Remarks: Instead of the quote (") each other character may be used as delimiter for the findstring and replacestring. Using the quote as delimiter finds text strings, that are not tokenized and therefore not part of a keyword.
CHANGE "LOOP" TO "OOPS" will not find the BASIC keyword **LOOP** , because the keyword is stored as token and not as text. However **CHANGE &LOOP& TO &OOPS&** will find and replace it (probably spoiling the program).

Example: Using **CHANGE**

```
CHANGE "XX$" TO "UU$", 2000-2700
CHANGE &IN& TO &OUT&
```

CHAR

Token: \$E0

Format: **CHAR** column, row, height, width, direction, string [, address of character set]

Usage: Displays text on a graphic screen. It can be used for all resolutions.

column is the start position of the output in horizontal direction. One column is 8 pixels wide, so a screen width of 320 has a column range 0 -> 39, while a width of 640 has a range of 0 -> 79.

row is the start position of the output in vertical direction. Other than column, its unit is pixel with top row having the value 0.

height is a factor applied to the vertical size of the characters. 1 is normal size (8 pixels) 2 is double size (16 pixels), and so on.

width is a factor applied to the horizontal size of the characters. 1 is normal size (8 pixels) 2 is double size (16 pixels), and so on.

direction controls the printing direction:

1: up
2: right
4: down
8: left

The optional **address of character set** can be used to select a character set different from the default character set at \$29800, which is the set with upper/lower characters.

string is a string constant or expression which will be printed.

Remarks: Control characters, for example: cursor movement codes, will be ignored (neither printed nor interpreted).

Example: Using **CHAR**

```
CHAR 304,196, 1,1,2, "MEGA 65"
```

will print the text "MEGA 65" on the centre of a 640 x 400 graphic screen.

CHR\$

Token: \$C1

Format: **CHR\$(numeric expression)**

Usage: Returns a string of length one character using the argument to insert the character having this value as PETSCII code.

Remarks: The argument range is 0 -> 255, so this function may also be used to insert control codes into strings. Even the NULL character, with code 0, is allowed.

CHR\$ is the inverse function to **ASC**.

Example: Using **CHR\$**

```
10 QUOTE$ = CHR$(34)
20 ESCAPE$ = CHR$(27)
30 PRINT QUOTE$;"MEGA 65";QUOTE$ : REM PRINT "MEGA 65"
40 PRINT ESCAPE$;"Q";          : REM CLEAR TO END OF LINE
```

CIRCLE

Token: \$E2

Format: **CIRCLE** *xcentre, ycentre, radius, [,solid]*

Usage: A special case of the **ELLIPSE** command using the same value for horizontal and vertical radius.

xcentre x coordinate of centre in pixels.

ycentre y coordinate of centre in pixels.

radius radius of the circle in pixels.

solid will fill the circle if not zero.

Remarks: The **CIRCLE** command is used to draw circles on screens with an aspect ratio 1:1 (for example: 320 x 200 or 640 x 400). On other resolutions (like: 640 x 200) the shape will degrade to an ellipse.

Example: Using **CIRCLE**

```
10 REM USE A 640 X 400 SCREEN
20 CIRCLE 320,200,100
30 REM DRAW CIRCLE IN THE CENTRE OF THE SCREEN
```

CLOSE

Token: \$A0

Format: **CLOSE channel**

Usage: Closes an input or output channel, that was established before by an **OPEN** command.

channel is a value in the range 0 -> 255.

Remarks: Closing open files before the program stops is very important, especially for output files. This command flushes output buffers and updates directory informations on disks. Failing to **CLOSE** can corrupt files and disks. BASIC does NOT automatically close channels or files when the program stops.

Example: Using **CLOSE**

```
10 OPEN 2,8,2,"TEST,S,W"  
20 PRINT#2,"TESTSTRING"  
30 CLOSE 2 : REM OMITTING CLOSE GENERATES A SPLAT FILE
```

CLR

Token: \$9C

Format: **CLR**

Usage: Resets all pointers, that are used for management of BASIC variables, arrays and strings. The runtime stack pointers are reset and the table of open channels is reset. A **RUN** command performs **CLR** automatically.

Remarks: **CLR** should not be used inside loops or subroutines because it destroys the return address. After a **CLR** all variables are unknown and will be initialized at the next usage.

Example: Using **CLR**

```
10 A=5: P$="MEGA 65"  
20 CLR  
30 PRINT A;P$  
  
0  
READY.
```

CMD

Token: \$9D

Format: **CMD channel** [,string]

Usage: Redirects the standard output from screen to the channel. This enables to print listings and directories or other screen outputs. It is also possible to redirect this output to a disk file or a modem.

channel must be opened by the **OPEN** command.

The optional **string** is sent to the channel before the redirection begins and can be used, for example, for printer setup escape sequences.

Remarks: The **CMD** mode is stopped by a **PRINT# channel** or by closing the channel with **CLOSE channel**. It is recommended to use a **PRINT# channel** before closing, to make sure, that the output buffer is flushed.

Example: Using **CMD** to print a program listing:

```
OPEN 4,4
LIST
PRINT#4
CLOSE 4
```

COLLECT

Token: \$F3

Format: **COLLECT** [**D drive**] [**U unit**]

Usage: Rebuilds the **BAM** (Block Availability Map) deleting splat files and marking unused blocks as free.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

Remarks: While this command is useful for cleaning the disk from splat files (for example: write files, that weren't properly closed) it is dangerous for disks with boot blocks or random access files. These blocks are not associated with standard disk files and will therefore be marked as free too and may be overwritten by further disk write operations.

Example: Using **COLLECT**

```
COLLECT
COLLECT U9
COLLECT D0, U9
```

COLLISION

Token: \$FE \$17

Format: **COLLISION** type [,linenumber]

Usage: Enables or disables an user programmed interrupt handler. A call without linenumber disables the handler, while a call with linenumber enables it. After the execution of **COLLISION** with linenumber a sprite collision of the same type, as specified in the **COLLISION** call, interrupts the BASIC program and perform a **GOSUB** to **linenumber** which is expected to contain the user code for handling sprite collisions. This handler must give control back with a **RETURN**.

type specifies the collision type for this interrupt handler:

1 = sprite - sprite collision

2 = sprite - data - collision

3 = light pen

linenumber must point to a subroutine which holds code for handling sprite collision and ends with a **RETURN**.

Remarks: It is possible to enable interrupt handler for all types, but only one can execute at any time. A interrupt handler cannot be interrupted by another interrupt handler. Functions like **BUMP**, **RSPPOS** and **LPEN** may be used for evaluation of the sprites which are involved and their positions.

Example: Using **COLLISION**

```
10 COLLISION 1,70 : REM ENABLE
20 SPRITE 1,1 : MOVSPR 1,120, 0 : MOVSPR 1,0#5
30 SPRITE 2,1 : MOVSPR 2,120,100 : MOVSPR 2,180#5
40 FOR I=1 TO 50000:NEXT
50 COLLISION 1 : REM DISABLE
50 END
70 REM SPRITE <-> SPRITE INTERRUPT HANDLER
80 PRINT "BUMP RETURNS";BUMP(1)
90 RETURN: REM RETURN FROM INTERRUPT
```

COLOR

Token: \$E7

Format: **COLOR** <ON|OFF>

Usage: Enables or disables handling of the character attributes on the screen. If **COLOR** is **ON**, the screen routines take care for both character RAM and attribute RAM. E.g. if the screen is scrolled for text, the attributes are scrolled too, so each character keeps his attribute or colour. If **COLOR** is **OFF**, the attribute or colour RAM is fixed and character movement is only done for screen characters. This speeds up screen handling, if moving characters with different colours is not intended.

Example: **COLOR ON** - with colour/attribute handling
COLOR OFF - no colour/attribute handling

CONCAT

Token: \$FE \$13

Format: **CONCAT** **appendfile** [,D drive#] **TO** **targetfile** [,D drive] [,U unit]

Usage: The **CONCAT** (concatenation) appends the contents of **appendfile** to the **targetfile**. Afterwards **targetfile** contains the contents of both files, while **appendfile** remains unchanged.

appendfile is either a quoted string, for example: **"data"** or a string expression in parentheses, for example: **(FN\$)**

targetfile is either a quoted string, for example: **"safe"** or a string expression in parentheses, for example: **(FS\$)**

If the disk unit has dual drives, it is possible to apply the **CONCAT** command to files, which are stored on different disks. In this case, it is necessary to specify the drive# for both files in the command. This is necessary too, if both files are stored on drive#1.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The **CONCAT** commands is executed in the DOS of the disk drive. Both files must exist and no pattern matching is allowed. Only sequential files of type **SEQ** may be concatenated.

Example: Using **CONCAT**

```
CONCAT "NEW DATA" TO "ARCHIVE" ,U9
CONCAT "ADDRESS",D0 TO "ADDRESS BOOK",D1
```

CONT

Token: \$9A

Format: **CONT**

Usage: Used to resume program execution after a break or stop caused by an **END** or **STOP** statement or by pressing the **STOP KEY**. This is a useful debug tool. The BASIC program may be stopped and variables can be examined and even changed. The **CONT** statement then resumes execution.

Remarks: **CONT** cannot be used, if the program stops due to errors. Also any editing of the program inhibits continuation. Stopping and continuation can spoil the screen output or interfere with input/output operations.

Example: Using **CONT**

```
10 I=I+1:GOTO 10
RUN

BREAK IN 10
READY.
PRINT I
947
CONT
```

COPY

Token: \$FE \$13

Format: **COPY** **source** [,D drives] **TO** **target** [,D drive] [,U unit]

Usage: Copies the contents of **source** to the **target**. It is used to copy either single files or, by using wildcard characters, multiple files.

source is either a quoted string, e.g. "**data**" or a string expression in parentheses, e.g. (**FN\$**).

target is either a quoted string, e.g. "**backup**" or a string expression in parentheses, e.g. (**FS\$**)

If the disk unit has dual drives, it is possible to copy files from disk to disk. In this case, it is necessary to specify the drive# for source and target in the command. This is necessary too, if both files are stored on drive# 1.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The **COPY** command is executed in the DOS of the disk drive. It can copy all regular file types (PRG, SEQ, USR, REL). The source file must exist, the target file must not exist. If source and target are on the same disk, the target filename must be different from the source file name.

Example: Using **COPY**

```
COPY "*",D0 TO D1      :REM COPY ALL FILES
COPY "CODES" TO "BACKUP" :REM COPY SINGLE FILE
COPY "*.TXT" TO D1      :REM PATTERN COPY
```

COS

Token: \$BE

Format: **COS**(numeric expression)

Usage: The **COS** function returns the cosine of the argument. The argument is expected in units of **[radians]**. The result is in the range (-1.0 to +1.0)

Remarks: An argument in units of **[degrees]** can be converted to **[radians]** by multiplication with $\pi/180$.

Example: Using **COS**

```
PRINT COS(0.7)
.764842187

X=60:PRINT COS(X *  $\pi$  / 180)
.500000001
```

DATA

Token: \$83

Format: **DATA** [list of constants]

Usage: Used to define constants which can be read by **READ** statements somewhere in the program. All type of constants (integer, real, strings) are allowed, but no expressions. Items are separated by commas. Strings containing commas, colons or spaces must be put in quotes.

A **RUN** command initializes the data pointer to the first item of the first **DATA** statement and advances it for every read item. It is in the responsibility of the programmer, that the type of the constant and the variable in the **READ** statement match. Empty items with no constant between commas are allowed and will be interpreted as zero for numeric variables and an empty string for string variables.

The **RESTORE** command may be used to set the data pointer to a specific line for subsequent readings.

Remarks: It is good programming style to put large amount of **DATA** statements at the end of the program. Otherwise **GOTO** and **GO-SUB** statements, with target lines lower than the current one, start their search for linenummer at the beginning of the program and have to skip through **DATA** lines wasting time.

Example: Using **DATA**

```
10 READ NA$, VE
20 READ N%:FOR I=2 TO N%:READ GL(I):NEXT I
30 PRINT "PROGRAM: ";NA$;"  VERSION: ";VE
40 PRINT "N-POINT GAUSS-LEGENDRE FACTORS E1":
50 FOR I=2 TO N%:PRINT I;GL(I):NEXT I
30 STOP
80 DATA "MEGA 65",1.1
90 DATA 5,0.5120,0.3573,0.2760,0.2252
```

DCLEAR

Token: \$FE \$15

Format: **DCLEAR** [,D drive] [,U unit]

Usage: Sends an initialise command to the specified unit and drive.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The DOS inside the disk unit will close all open files, clear all channels, free buffers and reread the BAM. This command should be used together with a **DCLOSE** to make sure, that the computer and the drive agree on the status, otherwise strange side effects may occur.

Example: Using **DCLEAR**

```
DCLOSE :DCLEAR
DCLOSE U9:DCLEAR U9
DCLOSE U9:DCLEAR D0, U9
```

DCLOSE

Token: \$FE \$0F

Format: **DCLOSE** [#channel] [,U unit]

Usage: Closes a single file or all files for the specified unit.

channel = channel # assigned with the **DOPEN** statement.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

The **DCLOSE** command is used either with a channel argument or a unit number, but never both.

Remarks: It is important to close all open files before the program ends. Otherwise buffers will not be freed and even worse, open write files will be incomplete (splat files) and no more usable.

Example: Using **DCLOSE**

```
DCLOSE#2 :REM CLOSE FILE ASSIGNED TO CHANNEL 2  
DCLOSE U9:REM CLOSE ALL FILES OPEN ON UNIT 9
```

DEC

Token: \$D1

Format: **DEC(string expression)**

Usage: Returns the decimal value of the argument, that is written as a hex string. The argument range is "0000" to "FFFF" or 0 to 65535 respectively. The argument must have 1-4 hex digits.

Remarks: Allowed digits in uppercase/graphics mode are:
0 1 2 3 4 5 6 7 8 9 A B C D E F and in lowercase/uppercase mode:
0 1 2 3 4 5 6 7 8 9 a b c d e f.

Example: Using **DEC**

```
PRINT DEC("D000")
53248
POKE DEC"600"),255
```

DEF FN

Token: \$96

Format: **DEF FN name(real variable)**

Usage: Defines a single statement user function with one argument of real type returning a real value. The definition must be executed before the function can be used in expressions. The argument is a dummy variable, which will be replaced by the argument in the function usage.

Remarks: The value of the dummy variable will not be changed and the variable may be used in other context without side effects.

Example: Using **DEF FN**

```
10 PD = π / 180
20 DEF FN CD(X)= COS(X*PD): REM COS FOR DEGREES
30 DEF FN SD(X)= SIN(X*PD): REM SIN FOR DEGREES
40 FOR D=0 TO 360 STEP 90
50 PRINT USING "###";D
60 PRINT USING " ###.##";FNCD(D);
70 PRINT USING " ###.##";FNSD(D)
80 NEXT D
RUN
 0 1.00 0.00
90 0.00 1.00
180 -1.00 0.00
270 0.00 -1.00
360 1.00 0.00
```

DELETE

Token: \$F7

Format: **DELETE** [**line range**]
 DELETE filename [,D drive] [,U unit] [,R]

Usage: Used either to delete a range of lines from the BASIC program or to delete a disk file.

line range consist of the first and the last line to delete or a single line number. If the first number is omitted, the first BASIC line is assumed. The second number in the range specifier defaults to the last BASIC line.

filename is either a quoted string, for example: **"safe"** or a string expression in parentheses, for example: **(FSS)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

R = Recover a previously deleted file. This will only work, if there were no write operations between deletion and recovery, which may have altered the contents of the file.

Remarks: The **DELETE filename** command works like the **SCRATCH filename** command.

Example: Using **DELETE**

```
DELETE 100      :REM DELETE LINE 100
DELETE 240-350  :REM DELETE ALL LINES FROM 240 TO 350
DELETE 500-     :REM DELETE FROM 500 TO END
DELETE -70      :REM DELETE FROM START TO 70

DELETE "DRM",U9 :REM DELETE FILE DRM ON UNIT 9
```

DIM

Token: \$86

Format: **DIM name(limits) [,name(limits)]...**

Usage: Declares the shape, the bounds and the type of a BASIC array. As a declaration statement it must be executed only once and before any usage of the declared arrays. An array can have one or more dimensions. One dimensional arrays are often called vectors while two or more dimensions define a matrix. The lower bound of a dimension is always zero, while the upper bound is declared. The rules for variable names apply for array names too. There are integer arrays, real arrays and string arrays. It is legal to use the same identifier for scalar variables and array variables. The left parenthesis after the name identifies array names.

Remarks: Integer arrays consume two bytes per element, real arrays five bytes and string arrays three bytes for the string descriptor plus the length of the string.
If an array identifier is used without previous declaration, an implicit declaration of an one dimensional array with limit 10 is performed.

Example: Using **DIM**

```
10 DIM A%(8) :REM ARRAY OF 9 ELEMENTS
20 DIM XX(2,3) :REM ARRAY OF 3x4 = 12 ELEMENTS
30 FOR I=0 TO 8:A%(I)=PEEK(256+I):NEXT
40 FOR I=0 TO 2:FOR J=0 TO 3:READ XX(I,J):NEXT J,I
50 END
60 DATA 1,-2,3,-4,5,-6,7,-8,9,-10,11,-12
```

DIRECTORY

Token: \$EE

Format: **DIRECTORY** [**filepattern**] [**R**] [**D drive**] [**U unit**]

Usage: Prints a listing of the specified disk and may be abbreviated to **DIR**.

The **R** (Recoverable) parameter includes files in the directory, which are flagged as deleted but are still recoverable.

filepattern is either a quoted string, e.g. **"da*"** or a string expression in parentheses, e.g. **(DI\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

Remarks: The command **DIRECTORY** is a synonym for **CATALOG** or **DIR** and produces the same listing. The **filepattern** can be used to restrict the listing. The wildcard characters **'*'** and **'?'** may be used. Adding a **",T="** to the pattern string, with T specifying a filetype P,S,U or R (for PRG,SEQ,USR,REL) restricts the output to that filetype.

Example: Using **DIRECTORY**

```
DIRECTORY
  0 "BLACK SMURF"    " BS  2A
508 "STORY PHOBOS"   SEQ
27  "C8096"          PRG
25  "C128"           PRG
104 BLOCKS FREE.

DIR ",T=S"
  0 "BLACK SMURF"    " BS  2A
508 "STORY PHOBOS"   SEQ
104 BLOCKS FREE.
```

DISK

Token: \$FE \$40

Format: **DISK command [,U unit]**

Usage: Sends a command string to the specified disk unit.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

command is a string expression.

Remarks: The command string is interpreted by the disk unit and must be compatible to the used DOS version. Read the disk drive manual for possible commands.

Example: Using **DISK**

```
DISK "I0" :REM INITIALIZE DISK IN DRIVE 0
DISK "U0>9" :REM CHANGE UNIT# TO 9
```

DLOAD

Token: \$F0

Format: **DLOAD filename [,D drive] [,U unit]**

Usage: "Disk LOAD" loads a file of type PRG into memory reserved for BASIC program source.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

Remarks: The load address, stored in the first two bytes of the file is ignored. The program is loaded into the BASIC memory. This enables loading of BASIC programs, that were saved on other computers with different memory configurations. After loading the program is relinked and ready to run or edit. It is possible to use DLOAD in a running program (Called overlay or chaining). Then the new loaded program replaces the current one and the execution starts automatically on the first line of the new program. Variables, arrays and strings from the current run are preserved and can be used by the new loaded program.

Example: Using **DLOAD**

```
DLOAD "APOCALYPSE"  
DLOAD "MEGA TOOLS",U9  
DLOAD (FN$),U(UN%)
```

DMA

Token: \$FE \$23

Format: **DMA command [,length, source, target, sub]**

Usage: The **DMA** ("Direct Memory Access") command is the fastest method to manipulate memory areas using the DMA controller.

command 0 = copy, 1 = mix, 2 = swap, 3 = fill

length = number of bytes

source = 24bit address of read area or fill byte

target = 24bit address of write area

sub = sub command

Remarks: The **DMA** controller has access to the whole 8 MB address range using 24 bit addresses. The block size is limited to 64K.

Example: Using **DMA**

```
DMA 3, 2000, 32,0, 2048,0 :REM FILL SCREEN WITH BLANKS
DMA 0, 2000, 2048,0, 16384,1 :REM COPY SCREEN TO $14000
```

DMODE

Token: \$FE \$35

Format: **DMODE jam,complement,inverse,stencil,style,thick**

Usage: "Display MODE" sets several parameter of the graphical context for drawing commands.

jam	0 - 1
complement	0 - 1
inverse	0 - 1
stencil	0 - 1
style	0 - 3
thick	1 - 8

DO

Token: \$EB

Format: **DO** ... **LOOP**
DO [<**UNTIL** | **WHILE**> <logical expr.>]
... statements [**EXIT**]
LOOP [<**UNTIL** | **WHILE**> <logical expr.>]

Usage: The **DO** and **LOOP** keywords define the start and end of the most versatile BASIC loop. Using **DO** and **LOOP** alone, without any modifiers creates an infinite loop, that can be left by the **EXIT** statement only. The loop can be controlled by adding an **UNTIL** or a **WHILE** statement after the **DO** or **LOOP**.

Remarks: **DO** loops may be nested. An **EXIT** statement exits the current loop only.

Example: Using **DO** and **LOOP**

```
10 PW$="":DO
20 GET A$:PW$=PW$+A$
30 LOOP UNTIL LEN(PW$)>7 OR A$=CHR$(13)

10 DO : REM WAIT FOR USER DECISION
20 GET A$
30 LOOP UNTIL A$='Y' OR A$='N' OR A$='y' OR A$='n'

10 DO WHILE ABS(EPS) > 0.001
20 GOSUB 2000 : REM ITERATION SUBROUTINE
30 LOOP

10 I%=0 : REM INTEGER LOOP 1 -> 100
20 DO I%=I%+1
30 LOOP WHILE I% < 101
```

DOPEN

Token: \$FE \$0D

Format: **DOPEN# lfn, filename [,L[reclen]] [,W] [,D drive] [,U unit]**

Usage: Opens a file for reading, writing or modifying.

lfn = logical file number

1 <= lfn <= 127: line terminator is CR

128 <= lfn <= 255: line terminator is CR LF

L indicates, that the file is a relative file, which is opened for read/write and random access. The reclength is mandatory for creating realative files. For existing relative files, the reclen is used as a safety check, if given.

W opens a file for write access. The file must not exist.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FNS)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8 .

Remarks: **DOPEN#** may be used to open all file types. The sequential file type **SEQ** is default. The relative file type **REL** is chosen by using the **L** parameter. Other file types must be specified in the filename, e.g. by adding **",P"** to the filename for program files or **",U"** for USR files.

The usage of the "save-and-replace" character '@' at the beginning of the filename is not recommended, because many Commodore disk drives have a bug, that can cause data loss when using this feature.

Example: Using **DOPEN**

```
DOPEN#5,"DATA",U9
DOPEN#130,(DD$),U(UN%)
DOPEN#3,"USER FILE,U"
DOPEN#2,"DATA BASE",L240
```

```
OPENN#4,"MYPROG,P" : REM OPEN PRG FILE
```

DPAT

Token: \$FE \$36

Format: **DPAT type [,number, pattern, ...]**

Usage: "Drawing PATtern" sets pattern of the graphical context for drawing commands.

type	0 - 63
number	1 - 4
pattern	0 - 255

DSAVE

Token: \$EF

Format: **DSAVE** filename [,D drive] [,U unit]

Usage: "Disk SAVE" saves a BASIC program to a file of type PRG.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FNS)**. The maximum length of the filename is 16 characters. If the first character of the filename is an at-sign '@' it is interpreted as a "save and replace" operation. It is dangerous to use this replace option on drives 1541 and 1571, because they contain the notorious "save and replace bug" in their DOS.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The **DVERIFY** can be used after **DSAVE** to check, if the saved program on disk is identical to the program in memory.

Example: Using **DSAVE**

```
DSAVE "ADVENTURE"  
DSAVE "ZORK-I",U9  
DSAVE "DUNGEON",D1,U10
```

DVERIFY

Token: \$FE \$14

Format: **DVERIFY filename [,D drive] [,U unit]**

Usage: "Disk VERIFY" compares a BASIC program in memory with a disk file of type PRG.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

Remarks: **DVERIFY** can only test for equality. It gives no information about the number or position of different valued bytes. The command exits either with the message **OK** or with **VERIFY ERROR**.

Example: Using **DVERIFY**

```
DVERIFY "ADVENTURE"  
DVERIFY "ZORK-I",U9  
DVERIFY "DUNGEON",D1,U10
```

EL

Format: **EL** is a reserved system variable

Usage: **EL** has the value of the line, where the latest BASIC error occurred or the value -1 if there was no error.

This variable is typically used in a TRAP routine, where the error line is taken from **EL**.

Example: Using **EL**

```
10 TRAP 100

100 IF ER>0 AND ER<42 THEN PRINT ERR$(ER);" ERROR"
110 PRINT " IN LINE";EL
120 RESUME
```

ELLIPSE

Token: \$FE \$30

Format: **ELLIPSE** **xcentre**, **ycentre**, **xradius**, **yradius**, [**solid**]

Usage: As the name says, it draws an ellipse.

xcentre x coordinate of centre in pixels.

ycentre y coordinate of centre in pixels.

xradius x radius of the ellipse in pixels.

yradius y radius of the ellipse in pixels.

solid will fill the ellipse if not zero.

Remarks: The **ELLIPSE** command is used to draw ellipses on screens with various resolutions. It can also be used to draw circles.

Example: Using **ELLIPSE**

```
10 REM USE A 640 X 400 SCREEN
20 ELLIPSE 320,200,100,150
30 REM DRAW ELLIPSE IN THE CENTRE
```

ELSE

Token: \$D5

Format: **IF expression THEN true clause ELSE false clause**

Usage: The **ELSE** keyword is part of an **IF** statement.

expression is a logical or numeric expression. A numerical expression is evaluated as **FALSE** if the value is zero and **TRUE** for any non zero value.

true clause are one or more statements starting directly after **THEN** on the same line. A linenumber after **THEN** performs a **GOTO** to that line.

false clause are one or more statements starting directly after **ELSE** on the same line. A linenumber after **ELSE** performs a **GOTO** to that line.

Remarks: The standard **IF ... THEN ... ELSE** structure is restricted to a single line. But the **true clause** or **false clause** may be expanded to several lines using a compound statement bracketed with the keywords **BEGIN** and **BEND**.

Example: Using **ELSE**

```
10 IF V < 0 THEN PRINT RED$;:ELSE PRINT BLACK$;  
20 PRINT V : REM PRINT NEGATIVE NUMBERS IN RED  
30 INPUT "END PROGRAM:(Y/N)";A$  
40 IF A$="Y" THEN END  
50 IF A$="N" THEN 10:ELSE 30
```

END

Token: \$80

Format: **END**

Usage: Ends the execution of the BASIC program. The **READY.** prompt appears and the computer goes into direct mode waiting for keyboard input.

Remarks: **END** does **not** clear channels or close files. Also variable definitions are still valid after **END**. The program may be continued with the **CONT** statement. After executing the very last line of the program **END** is executed automatically.

Example: Using **END**

```
10 IF V < 0 THEN END : REM NEGATIVE NUMBERS END THE PROGRAM
20 PRINT V
```

ENVELOPE

Token: \$FE \$0A

Format: **ENVELOPE** n, [attack,decay,sustain,release, waveform,pw]

Usage: Used to define the parameters for the synthesis of a musical instrument.

n = envelope slot (0 -> 9)

attack = attack rate (0 -> 15)

decay = decay rate (0 -> 15)

sustain = sustain rate (0 -> 15)

release = release rate (0 -> 15)

waveform = (0:triangle, 1:sawtooth, 2:square/pulse, 3:noise, 4:ring modulation)

pw = pulse width (0 -> 4095) for waveform = pulse.

There are 10 slots for storing tunes, preset with following values:

n	A	D	S	R	WF	PW	Instrument
0	0	9	0	0	2	1536	piano
1	12	0	12	0	1		accordion
2	0	0	15	0	0		calliope
3	0	5	5	0	3		drum
4	9	4	4	0	0		flute
5	0	9	2	1	1		guitar
6	0	9	0	0	2	512	harpsichord
7	0	9	9	0	2	2048	organ
8	8	9	4	1	2	512	trumpet
9	0	9	0	0	0		xylophone

Example: Using **ENVELOPE**

```
10 ENVELOPE 9,10,5,10,5,2,4000:PLAY "T9"
20 VOL 8
30 TEMPO 100
40 PLAY "C D E F G A B"
50 PLAY "U5 V1 C D E F G A B"
```

ERASE

Token: \$FE \$2A

Format: **ERASE filename** [,D drive] [,U unit] [,R]

Usage: Used to erase a disk file.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

R = Recover a previously erased file. This will only work, if there were no write operations between erasion and recovery, which may have altered the contents of the file.

Remarks: The **ERASE filename** command works like the **SCRATCH filename** command.

The success and the number of erased files can be examined by printing or using the system variable DS\$. The second last number, which reports the track number in case of an disk error, now reports the number of successfully erased files.

Example: Using **ERASE**

```
SCRATCH "DRM",U9 :REM SCRATCH FILE DRM ON UNIT 9
PRINT DS$
01, FILES SCRATCHED,01,00
SCRATCH "OLD*" :REM SCRATCH ALL FILES BEGINNING WITH "OLD"
PRINT DS$
01, FILES SCRATCHED,04,00
```

ER

Format: **ER** is a reserved system variable

Usage: **ER** has the value of the latest BASIC error occurred or the value -1 if there was no error.

This variable is typically used in a TRAP routine, where the error number is taken from **ER**.

Example: Using **ER**

```
10 TRAP 100

100 IF ER>0 AND ER<42 THEN PRINT ERR$(ER);" ERROR"
110 RESUME
```

ERR\$

Token: \$D3

Format: ERR\$(number)

Usage: Used to convert an error number to an error string.

number is a BASIC error number (1 -> 41).

This function is typically used in a TRAP routine, where the error number is taken from the reserved variable **ER**.

Remarks: Arguments out of range (1 -> 41) will produce an 'ILLEGAL QUANTITY' error.

Example: Using ERR\$

```
10 TRAP 100

100 IF ER>0 AND ER<42 THEN PRINT ERR$(ER);" ERROR"
110 RESUME
```

EXIT

Token: \$FD

Format: EXIT

Usage: Exits the current **DO .. LOOP** and continues execution at the first statement after the next **LOOP** statement.

Remarks: In nested loops **EXIT** exits only one loop continuing executing in the next outer loop if there is one.

Example: Using **EXIT**

```
10 DO
20 INPUT "ENTER YOUR AGE";AGE%
30 IF AGE% < 18 THEN EXIT
40 INPUT "ENTER YOUR CREDIT CARD #";CR$
50 LOOP UNTIL LEN(CR$) = 12
60 IF AGE% >= 18 THEN GOSUB 1000:REM VALIDATE CREDIT CARD
70 IF AGE% < 18 THEN PRINT "TOO YOUNG":END
```

EXP

Token: \$BD

Format: **EXP**(numeric expression)

Usage: The **EXP** (EXponential function) computes the value of the mathematical constant Euler's number **e** = **2.71828183** raised to the power of the argument.

Remarks: An argument greater than 88 produces an OVERFLOW ERROR:

Example: Using **EXP**

```
PRINT EXP(1)
2.71828183

PRINT EXP(0)
1

PRINT EXP(LOG(2))
2
```

FAST

Token: \$FE \$25

Format: **FAST**

Usage: Sets the system speed to maximum (3.58 MHz). The system default is **FAST**. However after using **SLOW** for access to slow devices, **FAST** can be used to return to fast mode.

Example: Using **FAST**

```
10 SLOW
20 GOSUB 1000:REM DO SOME SLOW I/O
30 FAST
```

FILTER

Token: \$FE \$03

Format: **FILTER** [**freq**, **lp**, **bp**, **hp**, **res**]

Usage: Sets the parameters for soundfilter.

freq = filter cut off frequency (0 -> 2047)

lp = low pass filter (0:off, 1:on)

bp = band pass filter (0:off, 1:on)

hp = high pass filter (0:off, 1:on)

resonance = resonance (0 -> 15)

Remarks: Missing parameter keep their current value. The effective filter is the sum of of all filter settings. This enables band reject and notch effects.

Example: Using **FILTER**

```
FILTER 1023,1,0,0,10 :REM LOW PASS  
FILTER 1023,0,1,0,10 :REM BAND PASS  
FILTER 1023,0,0,1,10 :REM HIGH PASS
```

FIND

Token: \$FE \$2B

Format: **FIND "string" [,from-to]**

Usage: **FIND** is an editor command and can be used in direct mode only. It searches the line range (if specified) or the whole BASIC program else. At each occurrence of the "find string" the line is listed with the string highlighted. The <NO-SCROLL> key can be used to pause the output.

Remarks: Instead of the quote (") each other character may be used as delimiter for the find string. Using the quote as delimiter finds text strings, that are not tokenized and therefore not part of a keyword.

FIND "LOOP" will not find the BASIC keyword **LOOP**, because the keyword is stored as token and not as text. However **FIND &LOOP&** will find it.

Example: Using **FIND**

```
FIND "XX$", 2000-2700
FIND &ER&
```

FN

Token: \$A5

Format: **FN name(numeric expression)**

Usage: The **FN** functions are user defined functions, that accept a numeric expression as argument and return a real value. They must be defined with **DEF FN** before the first usage.

Example: Using **FN**

```
10 PD =  $\pi$  / 180
20 DEF FN CD(X)= COS(X*PD): REM COS FOR DEGREES
30 DEF FN SD(X)= SIN(X*PD): REM SIN FOR DEGREES
40 FOR D=0 TO 360 STEP 90
50 PRINT USING "####";D
60 PRINT USING " ###.###";FNCD(D);
70 PRINT USING " ###.###";FNSD(D)
80 NEXT D
RUN
 0 1.00 0.00
90 0.00 1.00
180 -1.00 0.00
270 0.00 -1.00
360 1.00 0.00
```

FOR

Token: \$81

Format: **FOR** **index**=**start** **TO** **end** [**STEP** **step**] ... **NEXT** [**index**]

Usage: The **FOR** statement starts the definition of a BASIC loop with an index variable.

The **index** variable may be incremented or decremented by a constant value on each iteration. The default is to increment the variable by 1. The index variable must be a real variable.

The **start** value is used to initialize the index.

The **end** value is used at the end of the loop and controls, whether the next iteration will be started or the loop exited.

The **step** value defines the change applied to the index variable at the end of the loop. Positive step values increment it, while negative values decrement it. It defaults to 1.0 if not specified.

Remarks: For positive increments **end** must be greater or equal than **start**, for negative increments **end** must be less or equal than **start**.

It is bad programming style to change the value of the index variable inside the loop or to jump into or out of the loop body with **GOTO**.

Example: Using **FOR**

```
10 FOR D=0 TO 360 STEP 30
20 R = D * π / 180
30 PRINT D;R;SIN(R);COS(R);TAN(R)
40 NEXT D

10 DIM M(20,20)
20 FOR I=0 TO 20
30 FOR J=I TO 20
40 M(I,J) = I + 100 * J
50 NEXT J,I
```

FOREGROUND

Token: \$FE \$39

Format: **FOREGROUND** colour

Usage: Sets the foreground colour (text colour) of the screen to the argument, which must be in the range 1 to 16. (See colour table).

Example: **FOREGROUND 8** - select foreground colour yellow.

Colours: **Index and RGB values of colour palette**

index	red	green	blue	colour
1	0	0	0	black
2	15	15	15	white
3	15	0	0	red
4	0	15	15	cyan
5	15	0	15	magenta
6	0	15	0	green
7	0	0	15	blue
8	15	15	0	yellow
9	15	6	0	orange
10	10	4	0	brown
11	15	7	7	pink
12	5	5	5	dark grey
13	8	8	8	medium grey
14	9	15	9	light green
15	9	9	15	light blue
16	11	11	11	light grey

FRE

Token: \$B8

Format: **FRE(mode)**

Usage: Returns the number of free bytes for modes 0 and 1.

FRE(0) returns the number of free bytes in bank 0, which is used for BASIC program source.

FRE(1) returns the number of free bytes in bank 1, which is the bank for BASIC variables, arrays and strings. A usage of **FRE(1)** also triggers the "garbage collection", a process, that collects used strings at the top of the bank, thereby defragmenting string memory.

FRE(2) returns the number of expansion RAM banks, that are available RAM banks above the standard RAM banks 0 and 1, that are used by BASIC.

Example: Using **FRE**:

```
10 PM = FRE(0)
20 VM = FRE(1)
30 EM = FRE(2)
40 PRINT PM;" FREE FOR PROGRAM"
50 PRINT VM;" FREE FOR VARIABLES"
60 PRINT EM;" EXPANSION RAM BANKS"
```

GET

Token: \$A1

Format: **GET** string variable

Usage: Gets the next character from the keyboard queue. If the queue is empty an empty string is assigned to the variable, otherwise a one character string is created and assigned to the string variable. This command does not wait for keyboard input, so it's useful to check for key presses in regular intervals or loops.

Remarks: It is syntactically OK to use **GET** with a numerical variable, but this is dangerous, because hitting a non numerical key will produce an error message and stop the program. The command **GETKEY** is similar, but waits until a key was hit.

Example: Using **GET**:

```
10 DO: GET A$: LOOP UNTIL A$ <> ""
40 IF A$ = "W" THEN 1000 :REM GO NORTH
50 IF A$ = "A" THEN 2000 :REM GO WEST
60 IF A$ = "S" THEN 3000 :REM GO EAST
70 IF A$ = "Z" THEN 4000 :REM GO SOUTH
80 IF A$ = CHR$(13) THEN 5000 :REM RETURN
90 GOTO 10
```

GET#

Token: \$A1 '#'

Format: **GET# channel, list of string variables**

Usage: Reads as many bytes as necessary from the channel argument and assigns strings of length one to each variable in the list. This is useful to read characters or bytes from an input stream one by one.

Remarks: All values from 0 to 255 are valid, so this command can also be used to read binary data. A value of 0 generates a string of length 1 containing CHR\$(0) as character value.

Example: Using **GET#**:

```
10 OPEN 2,8,0,"$0,P"           :REM OPEN CATALOG
15 IF DS THEN PRINT DS$: STOP :REM CAN'T READ
20 GET#2,D$,D$                  :REM DISCARD LOAD ADDRESS
25 DO                           :REM LINE LOOP
30 : GET#2,D$,D$                :REM DISCARD LINE LINK
35 : IF ST THEN EXIT            :REM END-OF-FILE
40 : GET#2,L$,H$                :REM FILE SIZE BYTES
45 : S=ASC(L$) + 256*ASC(H$)    :REM FILE SIZE
45 : LINE INPUT#2, F$           :REM FILE NAME
50 : PRINT S;F$                 :REM PRINT FILE ENTRY
55 LOOP
60 CLOSE 2
```

GETKEY

Token: \$A1 \$F9 (GET token and KEY token)

Format: **GETKEY** string variable

Usage: Gets the next character from the keyboard queue. If the queue is empty the program waits until a key is hit. Then a one character string is created and assigned to the string variable.

Remarks: It is syntactically OK to use **GETKEY** with a numerical variable, but this is dangerous, because hitting a non numerical key will produce an error message and stop the program.

Example: Using **GETKEY**:

```
10 GETKEY A$ :REM WAIT AND GET CHARACTER
40 IF A$ = "W" THEN 1000 :REM GO NORTH
50 IF A$ = "A" THEN 2000 :REM GO WEST
60 IF A$ = "S" THEN 3000 :REM GO EAST
70 IF A$ = "Z" THEN 4000 :REM GO SOUTH
80 IF A$ = CHR$(13) THEN 5000 :REM RETURN
90 GOTO 10
```

GO64

Token: \$CB \$36 \$34 (GO token and 64)

Format: **GO64**

Usage: Switches the computer to the C64 compatible mode. In direct mode a security prompt "ARE YOU SURE?" is printed, which must be responded with 'Y' to continue.

Example: Using **GO64**:

```
GO64
ARE YOU SURE?
```

GOSUB

Token: \$8D

Format: **GOSUB** line

Usage: The **GOSUB** (GOto SUBroutine) command continues program execution at the given BASIC line number, saving the current BASIC program counter and line number on the runtime stack. This enables the resume of the execution after the **GOSUB** statement, once a **RETURN** statement in the called subroutine was executed. Calls to subroutines via **GOSUB** may be nested but the end of the subroutine code must always be a **RETURN**. Otherwise a stack overflow may occur.

Remarks: Unlike other programming languages, this BASIC version does not support arguments or local variables for subroutines. Programs can be optimised by grouping subroutines at the beginning of the program source. The **GOSUB** calls will then have low line numbers with only few digits to decode. Also the subroutines will be found faster, because the search for subroutines starts very often at the start of the program.

Example: Using **GOSUB**:

```
10 GOTO 100 :REM TO MAIN PROGRAM
20 REM *** SUBROUTINE DISK STATUS CHECK ***
30 DD=DS:IF DD THEN PRINT "DISK ERROR";DS$
40 RETURN
50 REM *** SUBROUTINE PROMPT Y/N ***
60 DO:INPUT "CONTINUE (Y/N)";A$
70 LOOP UNTIL A$="Y" OR A$="N"
80 RETURN
90 *** MAIN PROGRAM ***
100 DOPEN#2,"BIG DATA"
110 GOSUB 30: IF DD THEN DCLOSE#2:GOSUB 60:REM ASK
120 IF A$="N" THEN STOP
130 GOTO 100: REM RETRY
```

GOTO

Token: \$89 (GOTO) or \$CB \$A4 (GO TO)

Format: **GOTO** line
GO TO line

Usage: Continues program execution at the given BASIC line number. The **GOTO** command written as a single word executes faster than the **GO TO** command.

Remarks: The new line number will be searched by scanning the BASIC source linearly upwards. If the target line number is higher than the current one, the search starts from the current line upwards. If the target line number is lower, the search starts from the start of the program. Knowing this mechanism it is possible to optimise the runtime by grouping often used targets at the start of the program.

Example: Using **GOTO**:

```
10 GOTO 100 :REM TO MAIN PROGRAM
20 REM *** SUBROUTINE DISK STATUS CHECK ***
30 DD=DS:IF DD THEN PRINT "DISK ERROR";DS$
40 RETURN
50 REM *** SUBROUTINE PROMPT Y/N ***
60 DO:INPUT "CONTINUE (Y/N)";A$
70 LOOP UNTIL A$="Y" OR A$="N"
80 RETURN
90 *** MAIN PROGRAM ***
100 DOPEN#2,"BIG DATA"
110 GOTO 30: IF DD THEN DCLOSE#2:GOTO 60:REM ASK
120 IF A$="N" THEN STOP
130 GOTO 100: REM RETRY
```

GRAPHIC

Token: \$DE

Format: **GRAPHIC CLR**

Usage: Initialises the BASIC graphic system. It clears the graphics memory and screen and sets all parameters of the graphics context to the default values.

Remarks: A second form of the **GRAPHIC** command, which serves as an interface to internal subroutines may be added later.

Example: Using **GRAPHIC**:

```
10 GRAPHIC CLR      :REM INITIALIZE
20 SCREEN DEF 1,1,1,2 :REM 640 X 400 X 2
30 SCREEN SET 1,1    :REM VIEW IT
40 SCNCLR 0          :REM CLEAR SCREEN
50 LINE 50,50,590,350 :REM DRAW LINE
```

HEADER

Token: \$F1

Format: **HEADER** **diskname** [,**lid**] [,**D drive**] [,**U unit**]

Usage: Used to format or clear a diskette or disk.

diskname is either a quoted string, e.g. "**data**" or a string expression in parentheses, e.g. (**DN\$**) The maximum length of the diskname is 16 characters.

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: For new diskettes or disks, which are not already formatted it is absolutely necessary to specify the disk ID with the parameter **lid**. This switches the format command to the full format, which writes sector IDs and erases all contents. This will need some time, because every block on the disk will be written. If the **lid** parameter is omitted, a quick format will be performed. This is only possible, if the disk is formatted already. A quick format writes a new disk name and clears the block allocation map, marking all blocks as free. The disk ID is not changed, the blocks are not overwritten, so contents may be recovered with the **ERASE R** command.

Example: Using **HEADER**

```
HEADER "ADVENTURE",IBS
HEADER "ZORK-I",U9
HEADER "DUNGEON",D1,U10
```

HELP

Token: \$EA

Format: **HELP**

Usage: When the BASIC program stops due to an error, the **HELP** command can be used to list the erroneous line and highlight the statement, that caused the error stop.

Remarks: Displays BASIC errors. For errors in disk I/O one should print the disk status variable **DS** or the disk status string **DS\$**.

Example: Using **HELP**

```
10 A=1.E20
20 B=A+A:C=EXP(A):PRINT A,B,C
RUN

?OVERFLOW ERROR IN 20
READY.
HELP

20 B=A+A:C=EXP(A):PRINT A,B,C
```

The erroneous statement is highlighted or underlined like:
20 B=A+A:C=EXP(A):PRINT A,B,C

HEX\$

Token: \$D2

Format: HEX\$(numeric expression)

Usage: Returns a four character string in hexadecimal notation converted from the argument. The argument must be in the range 0 -> 65535 corresponding to the hex numbers 0000 -> FFFF.

Remarks: If real numbers are used as arguments, the fractional part will be cut off, not rounded.

Example: Using HEX\$:

```
PRINT HEX$(10),HEX$(100),HEX$(1000.9)
000A      0064      03E8
```

HIGHLIGHT

Token: \$FE \$39

Format: **HIGHLIGHT colour**

Usage: Sets the colour to be used for the "highlight" text attribute. The colour index must be in the range 1 to 16. (See colour table).

Remarks: The highlight text attribute is used to mark text in listings generated by the **HELP FIND CHANGE** commands.

Example: **HIGHLIGHT 8** - select highlight colour yellow.

Colours: **Index and RGB values of colour palette**

index	red	green	blue	colour
1	0	0	0	black
2	15	15	15	white
3	15	0	0	red
4	0	15	15	cyan
5	15	0	15	magenta
6	0	15	0	green
7	0	0	15	blue
8	15	15	0	yellow
9	15	6	0	orange
10	10	4	0	brown
11	15	7	7	pink
12	5	5	5	dark grey
13	8	8	8	medium grey
14	9	15	9	light green
15	9	9	15	light blue
16	11	11	11	light grey

IF

Token: \$8B

Format: **IF expression THEN true clause ELSE false clause**

Usage: Starts a conditional execution statement.

expression is a logical or numeric expression. A numerical expression is evaluated as **FALSE** if the value is zero and **TRUE** for any non zero value.

true clause are one or more statements starting directly after **THEN** on the same line. A linenumber after **THEN** performs a **GOTO** to that line.

false clause are one or more statements starting directly after **ELSE** on the same line. A linenumber after **ELSE** performs a **GOTO** to that line.

Remarks: The standard **IF ... THEN ... ELSE** structure is restricted to a single line. But the **true clause** or **false clause** may be expanded to several lines using a compound statement bracketed with the keywords **BEGIN** and **BEND**.

Example: Using **IF**

```
10 IF V < 0 THEN PRINT RED$;:ELSE PRINT BLACK$;  
20 PRINT V : REM PRINT NEGATIVE NUMBERS IN RED  
30 INPUT "END PROGRAM:(Y/N)";A$  
40 IF A$="Y" THEN END  
50 IF A$="N" THEN 10:ELSE 30
```

INPUT

Token: \$85

Format: **INPUT** [**prompt** <,|;>] **variable list**

Usage: Prints an optional prompt string and question mark to the screen, flashes the cursor and waits for user input from the keyboard.

prompt = string expression to be printed as prompt. It may be omitted.

If the separator between prompt and variable list is a comma, the cursor is placed directly after the prompt. If the separator is a semicolon, a question mark and a space is added to the prompt.

variable list = list of one or more variables, that receive the input.

The input will be processed after the user hits RETURN.

Remarks: The user must take care to enter the correct type of input matching variable types. Also the number of input items must match the number of variables. Entering non numeric characters for integer or real variables will produce a TYPE MISMATCH ERROR. Strings for string variables have to be put in quotes if they contain spaces or commas.

Many programs, that need a safe input routine use **LINE INPUT** and use an own parser, in order to avoid program breaks by wrong user input.

Example: Using **INPUT**:

```
10 DIM N$(100),A%(100),S$(100):
20 DO
30 INPUT "NAME, AGE, SEX";NA$,AG%,SE$
40 IF NA$="" THEN 30
50 IF NA$="END" THEN EXIT
60 IF AG% < 18 OR AG% > 100 THEN PRINT "AGE?":GOTO 30
70 IF SE$ <> "M" AND SE$ <> "F" THEN PRINT "SEX?":GOTO 30
80 REM CHECK OK: ENTER INTO ARRAY
90 N$(N)=NA$:A%(N)=AG%:S$(N)=SE$:N=N+1
100 LOOP UNTIL N=100
110 PRINT "RECEIVED";N;" NAMES"
```

INPUT#

Token: \$84

Format: **INPUT# channel, variable list**

Usage: Reads a record from an input device, e.g. a disk file or a RS232 device and assigns the read data to the variables in the list.

channel = channel number assigned by a **DOPEN** or **OPEN** command.

variable list = list of one or more variables, that receive the input.

The input record must be terminated by a RETURN character and must be not longer than the input buffer (160 characters).

Remarks: The type and number of data in a record must match the variable list. Reading non numeric characters for integer or real variables will produce a FILE DATA ERROR. Strings for string variables have to be put in quotes if they contain spaces or commas. The command **LINE INPUT#** may be used to read a whole record into a single string variable.

Example: Using **INPUT#**:

```
10 DIM M$(100),A$(100),S$(100):
20 DOPEN#2,"DATA"
30 FOR I=0 TO 100
40 INPUT#2,M$(I),A$(I),S$(I)
50 IF ST=64 THEN 80:REM END OF FILE
60 IF DS THEN PRINT DS$:GOTO 80:REM DISK ERROR
70 NEXT I
80 DCLOSE#2
110 PRINT "READ";I;" RECORDS"
```

INSTR

Token: \$D4

Format: INSTR(haystack, needle [,start])

Usage: Locates the position of the string expression "needle" in the string expression "haystack" and returns the index of the first occurrence or zero, if there is no match.

The string expression **haystack** is searched for the occurrence of the string expression **needle**.

The optional argument **start** is an integer expression, which defines the starting position for the search in **haystack**. If not present it defaults to one.

Remarks: If either string is empty or there is no match the function returns zero.

Example: Using INSTR:

```
I = INSTR("ABCDEF","CD")      : REM I = 3
I = INSTR("ABCDEF","XY")      : REM I = 0
I = INSTR("ABCDEF","E",3)     : REM I = 5
I = INSTR("ABCDEF","E",6)     : REM I = 0
I = INSTR(A$+B$,C$)
```

INT

Token: \$B5

Format: **INT**(numeric expression)

Usage: Searches the greatest integer value, that is less or equal to the argument and returns this value as a real number. This function is **NOT** limited to the typical 16-bit integer range (-32768 -> 32767), because it uses real arithmetic. The allowed range is therefore determined by the size of the real mantissas (32-bit) : (-2147483648 -> 2147483647).

Remarks: It is not necessary to use the **INT** function for assigning real values to integer variables, because this conversion will be done implicitly, but then for the 16-bit range.

Example: Using **INT**:

```
X = INT(1.9)      :REM X = 1
X = INT(-3.1)     :REM X = -4
X = INT(100000.5) :REM X = 100000
NX = INT(100000.5) :REM ?ILLEGAL QUANTITY ERROR
```

JOY

Token: \$CF

Format: JOY(port)

Usage: Returns the state of the joystick for the selected port (1 or 2). Bit 7 contains the state of the fire button. The stick can be moved in eight directions, which are numbered clockwise starting at the upper position.

	left	centre	right
up	8	1	2
centre	7	0	3
down	6	5	4

Example: Using JOY:

```
10 N = JOY(1)
20 IF N AND 128 THEN PRINT "FIRE! ";
30 REM          N  NE  E  SE  S  SW  W  NW
40 ON N AND 15 GOSUB 100,200,300,400,500,600,700,800
50 GOTO 10
100 PRINT "GO NORTH" :RETURN
200 PRINT "GO NORTHEAST":RETURN
300 PRINT "GO EAST" :RETURN
400 PRINT "GO SOUTHEAST":RETURN
500 PRINT "GO SOUTH" :RETURN
600 PRINT "GO SOUTHWEST":RETURN
700 PRINT "GO WEST" :RETURN
800 PRINT "GO NORTHWEST":RETURN
```

KEY

Token: \$F9

Format: **KEY [ON | OFF | number, string]**

Usage: The function keys can either send their keycode when pressed, or a string assigned to this key. After power up or reset this feature is activated and the keys have default assignments.

KEY OFF: switch off function key strings. The keys will send their character code if pressed.

KEY ON: switch on function key strings. The keys will send assigned strings if pressed.

KEY: list current assignments.

KEY number, string assigns the string to the key with that number.

Default assignments:

key	number	string
F1	1	"GRAPHIC"
F2	2	"DLOAD"+CHR\$(34)
F3	3	"DIRECTORY"+CHR\$(13)
F4	4	"SCNCLR"+CHR\$(13)
F5	5	"DSAVE"+CHR\$(34)
F6	6	"RUN"+CHR\$(13)
F7	7	"LIST"+CHR\$(13)
F8	8	"MONITOR"+CHR\$(13)
HELP	15	"HELP"+CHR\$(13)
RUN	16	"RUN"+CHR\$(34)+"*"+CHR\$(34)+CHR\$(13)

Remarks: The sum of the lengths of all assigned strings must not exceed 240 characters. Special characters like RETURN or QUOTE are entered using their codes with the CHR\$(code) function.

Example: Using **KEY**:

```
KEY ON           :REM ENABLE  FUNCTION KEYS
KEY OFF          :REM DISABLE FUNCTION KEYS
KEY              :REM LIST ASSIGNMENTS
KEY 2,"PRINT π"+CHR$(14) :REM ASSIGN PRINT PI TO F2
```

LEFT\$

Token: \$C8

Format: LEFT\$(string, n)

Usage: Returns a string containing the first **n** characters from the argument **string**. If the length of **string** is equal or less than **n**, the result string will be identical to the argument string.

string = a string expression

n = a numeric expression (0 -> 255)

Remarks: Empty strings and zero lengths are legal values.

Example: Using LEFT\$:

```
PRINT LEFT$("MEGA-65",4)
MEGA
```

LEN

Token: \$C3

Format: **LEN**(string)

Usage: Returns the length of the string.

string = a string expression

Remarks: Unprintable characters and even the NULL character are counted too.

Example: Using **LEN**:

```
PRINT LEN("MEGA-65"+CHR$(13))  
8
```

LET

Token: \$88

Format: **LET variable = expression**

Usage: The **LET** statement is obsolete and not needed. Assignment to variables can be done without using **LET**.

Example: Using **LET**:

```
LET A=5 :REM LONGER AND SLOWER  
A=5 :REM SHORTER AND FASTER
```

LINE

Token: \$E5

Format: **LINE** **xbeg,ybeg,xend,yend**

Usage: Draws a line on the current graphics screen from the coordinate (xbeg/ybeg) to the coordinate (xend/yend). All currently defined modes and values of the graphic context are used.

Example: Using **LINE**:

```
10 GRAPHIC CLR      :REM INITIALIZE
20 SCREEN DEF 1,1,1,2 :REM 640 X 400 X 2
30 SCREEN SET 1,1    :REM VIEW IT
40 SCNCLR 0          :REM CLEAR SCREEN
50 LINE 50,50,590,350 :REM DRAW LINE
```

LIST

Token: \$9B

Format: **LIST** [**line range**]

Usage: Used to list a range of lines from the BASIC program.

line range consist of the first and the last line to list or a single line number. If the first number is omitted, the first BASIC line is assumed. The second number in the range specifier defaults to the last BASIC line.

Remarks: The **LIST** command's output can be redirected to other devices via the **CMD** command.

Example: Using **LIST**

```
LIST 100      :REM LIST LINE 100
LIST 240-350  :REM LIST ALL LINES FROM 240 TO 350
LIST 500-     :REM LIST FROM 500 TO END
LIST -70      :REM LIST FROM START TO 70
```

LOAD

Token: \$93

Format: **LOAD filename [,U unit [,flag]]**

Usage: This command is obsolete in BASIC-10, where the commands **DLOAD** and **BLOAD** are better alternatives.

The **LOAD** loads a file of type PRG into RAM bank 0, which is also used for BASIC program source.

filename is either a quoted string, e.g. **"prog"** or a string expression.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

If **flag** has a non zero value, the file is loaded to the address, which is read from the first two bytes of the file. Otherwise it is loaded to the start of BASIC memory and the load address in the file is ignored.

Remarks: This command is implemented in BASIC-10 to keep it backward compatible to BASIC-2.

Example: Using **LOAD**

```
LOAD "APOCALYPSE"  
LOAD "MEGA TOOLS",9  
LOAD "*",8,1
```

LOCATE

Token: \$E6

Format: **LOCATE** x,y

Usage: Moves the graphical cursor to the specified position on the current graphic screen.

Remarks: The graphical cursor is not visible, it's just the starting point for follow up graphics commands. The current position can be examined with the **RDOT** function.

Example: Using **LOCATE**

```
LOCATE 8,16 :REM set cursor to X=8 and Y=16
```

LOG

Token: \$BC

Format: **LOG**(numeric expression)

Usage: Computes the value of the natural logarithm of the argument. The natural logarithm uses Euler's number **e** = **2.71828183** as base, not the number 10 which is typically used in log functions on a pocket calculator.

Remarks: The log function with base 10 can be computed by dividing the result by log(10).

Example: Using **LOG**

```
PRINT LOG(1)
0

PRINT LOG(0)
?ILLEGAL QUANTITY ERROR

PRINT LOG(4)
1.38629436

PRINT LOG(100) / LOG(10)
2
```

LOOP

Token: \$EC

Format: **DO ... LOOP**
DO [<UNTIL | WHILE> <logical expr.>]
... statements [**EXIT**]
LOOP [<UNTIL | WHILE> <logical expr.>]

Usage: The **DO** and **LOOP** keywords define the start and end of the most versatile BASIC loop. Using **DO** and **LOOP** alone, without any modifiers creates an infinite loop, that can be left by the **EXIT** statement only. The loop can be controlled by adding an **UNTIL** or a **WHILE** statement after the **DO** or **LOOP**.

Remarks: **DO** loops may be nested. An **EXIT** statement exits the current loop only.

Example: Using **DO** and **LOOP**

```
10 PW$="":DO
20 GET A$:PW$=PW$+A$
30 LOOP UNTIL LEN(PW$)>7 OR A$=CHR$(13)

10 DO : REM WAIT FOR USER DECISION
20 GET A$
30 LOOP UNTIL A$='Y' OR A$='N' OR A$='y' OR A$='n'

10 DO WHILE ABS(EPS) > 0.001
20 GOSUB 2000 : REM ITERATION SUBROUTINE
30 LOOP

10 I%=0 : REM INTEGER LOOP 1 -> 100
20 DO I%=I%+1
30 LOOP WHILE I% < 101
```

LPEN

Token: \$CE \$04

Format: **LPEN**(coordinate)

Usage: This function requires the use of a CRT monitor or TV and a light pen. It will not work with a LCD or LED screen. The lightpen must be connected to port 1.

LPEN(0) returns the X position of the lightpen, the range is 60 -> 320.

LPEN(1) returns the Y position of the lightpen, the range is 50 -> 250.

Remarks: The X resolution is two pixels, **LPEN(0)** returns therefore only even numbers. A bright background colour is needed to trigger the lightpen. The **COLLISION** statement may be used to install an interrupt handler.

Example: Using **LPEN**

```
PRINT LPEN(0),LPEN(1) :REM PRINT LIGHTPEN COORDINATES
```

MID\$

Token: \$CA

Format: **variable\$ = MID\$(string, index, n)**
MID\$(string, index, n) = string expression

Usage: **MID\$** can be used either as a function, which returns a string or as a statement for inserting substrings into an existing string.

string = a string expression

index = start index (0 -> 255)

n = length of substring (0 -> 255)

Remarks: Empty strings and zero lengths are legal values.

Example: Using **MID\$**:

```
10 A$ = "MEGA-65"  
20 PRINT MID$(A$,3,4)  
30 MID$(A$,5,1) = "+"  
40 PRINT A$  
RUN  
GA-6  
MEGA+65
```

MONITOR

Token: \$FA

Format: **MONITOR**

Usage: Calls the machine language monitor program, which is mainly used for debugging.

Remarks: Using the **MONITOR** requires knowledge of the CSG4510 / 6502 / 6510 CPU and the assembler language.

Example: Using **MONITOR**:

```
MONITOR
```

MOUSE

Token: \$FE \$3E

Format: **MOUSE ON** [,port [,sprite [,pos]]]
MOUSE OFF

Usage: Enables the mouse driver and connects the mouse at the specified port with the mouse pointer sprite.

port = mouse port 1, 2 (default) or 3 (both).

sprite = sprite number for mouse pointer (default 0).

pos = initial mouse position (x,y).

The **MOUSE OFF** command disables the mouse driver and frees the associated sprite.

Remarks: The "hot spot" of the mouse pointer is the upper left pixel of the sprite.

Example: Using **MOUSE**:

```
REM LOAD DATA INTO SPRITE #0 BEFORE USING IT
MOUSE ON, 1      :REM ENABLE MOUSE WITH SPRITE #0
MOUSE OFF       :REM DISABLE MOUSE
```

MOVSPR

Token: \$FE \$06

Format: **MOVSPR sprite, x, y**
MOVSPR sprite, <+|->xrel, <+|->yrel
MOVSPR sprite, angle # speed

Usage: **MOVSPR** performs, depending on the argument format, three different tasks:

The first form **MOVSPR sprite, x, y** uses no signs for the arguments and sets the absolute position of the sprite to the screen pixel coordinates **x** and **y**.

The second form **MOVSPR sprite, <+|->xrel, <+|->yrel** uses signs '+' or '-' to indicate a relative displacement to the current position.

The third form **MOVSPR sprite, angle # speed** does not set the position of sprite **n**, but defines motion parameters. The format is recognized by putting a hash sign '#' between the last two arguments.

sprite = sprite number

x = absolute screen coordinate [pixel].

y = absolute screen coordinate [pixel].

xrel = relative screen coordinate [pixel].

yrel = relative screen coordinate [pixel].

angle = direction for sprite movement [degrees]. 0 = up, 90 = right, 180 = down, 270 = left.

speed = speed of movement (0 -> 15).

Remarks: The "hot spot" is the upper left pixel of the sprite.

Example: Using **MOVSPR**:

```
10 SPRITE 1,1      :REM TURN SPRITE 1 ON
20 MOVSPR 1,50,50  :REM SET SPRITE 1 to (50,50)
30 MOVSPR 1,45#5   :REM MOVE SPRITE 1 WITH SPEED 5 TO UPPER RIGHT
```

NEW

Token: \$A2

Format: **NEW**
NEW RESTORE

Usage: Resets all BASIC parameters to their default values. After **NEW** the maximum RAM is available for program and data storage.

Because **NEW** resets parameters and pointers, but does not physically overwrite the address range of a BASIC program, that was in memory before **NEW**, it is possible to recover the program. If there were no **LOAD** operations or editing after the **NEW** command, the program can be restored with the command **NEW RESTORE**.

Example: Using **NEW**:

```
NEW          :REM RESET BASIC
NEW RESTORE :REM TRY TO RECOVER NEW'ED PROGRAM
```

NEXT

Token: \$82

Format: **FOR index=start TO end [STEP step] ... NEXT [index]**

Usage: Terminates the definition of a BASIC loop with an index variable.

The **index** variable may be incremented or decremented by a constant value **step** on each iteration. The default is to increment the variable by 1. The index variable must be a real variable.

The **start** value is used to initialize the index.

The **end** value is used at the end of the loop and controls, whether the next iteration will be started or the loop exited.

The **step** value defines the change applied to the index variable at the end of the loop. Positive step values increment it, while negative values decrement it. It defaults to 1.0 if not specified.

Remarks: The **index** variable after **NEXT** is optional. If no variable is specified, the variable for the current loop is assumed. Several consecutive **NEXT** statements may be combined by specifying the indexes in a comma separated list. For **NEXT I:NEXT J:NEXT K** the statement **NEXT I,J,K** is equivalent.

Example: Using **NEXT**

```
10 FOR D=0 TO 360 STEP 30
20 R = D * π / 180
30 PRINT D;R;SIN(R);COS(R);TAN(R)
40 NEXT D

10 DIM M(20,20)
20 FOR I=0 TO 20
30 FOR J=I TO 20
40 M(I,J) = I + 100 * J
50 NEXT J,I
```

NOT

Token: \$A8

Format: **NOT** operand

Usage: Performs a bitwise logical NOT operation on a 16 bit value. Integer operands are used as they are. Real operands are converted to a signed 16 bit integer. Logical operands are converted to 16 bit integer using \$FFFF, decimal -1 for TRUE and \$0000, decimal 0, for FALSE.

NOT 0 -> 1

NOT 1 -> 0

Remarks: The result is of integer type. If the result is used in a logical context, the value of 0 is regarded as FALSE, all other, nonzero values are regarded as TRUE.

Example: Using **NOT**

```
PRINT NOT 3
-4
PRINT NOT 64
-65
```

In most cases the **NOT** will be used in **IF** statements.

```
OK = C < 256 AND C >= 0
IF (NOT OK) THEN PRINT "NOT A BYTE VALUE"
```

OFF

Token: \$FE \$24

Format: keyword **OFF**

Usage: **OFF** is a secondary keyword used in combination with primary keywords like **COLOR, KEY, MOUSE**.

Remarks: The keyword **OFF** cannot be used on its own.

Example: Using **OFF**

```
COLOR OFF :REM DISABLE SCREEN COLOUR  
KEY OFF  :REM DISABLE FUNCTION KEY STRINGS  
MOUSE OFF :REM DISABLE MOUSE DRIVER
```

ON

Token: \$9 1

Format: **ON expression GOSUB line list**
ON expression GOTO line list
keyword **ON**

Usage: The **ON** keyword starts either a computed **GOSUB** or **GOTO** statement. Dependent on the value of the expression, the target for the **GOSUB** or **GOTO** is chosen from the table of line addresses at the end of the statement.

As a secondary keyword, **ON** is used in combination with primary keywords like **COLOR**, **KEY**, **MOUSE**.

expression is a positive numeric value. Real values are cut to integer.

line list is a comma separated list of valid line numbers.

Remarks: Negative values for **expression** will stop the program with an error message. The **line list** specifies the targets for values of 1,2,3,...

An expression value of zero or a value, that is greater than the number of target lines will do nothing and continue program execution with the next statement.

Example: Using **ON**

```
10 COLOR ON :REM ENABLE SCREEN COLOUR
20 KEY ON :REM ENABLE FUNCTION KEY STRINGS
30 MOUSE ON :REM ENABLE MOUSE DRIVER
40 N = JOY(1):IF N AND 128 THEN PRINT "FIRE! ";
60 REM          N NE E SE S SW W NW
70 ON N AND 15 GOSUB 100,200,300,400,500,600,700,800
80 GOTO 40

100 PRINT "GO NORTH" :RETURN
200 PRINT "GO NORTHEAST":RETURN
300 PRINT "GO EAST" :RETURN
400 PRINT "GO SOUTHEAST":RETURN
500 PRINT "GO SOUTH" :RETURN
600 PRINT "GO SOUTHWEST":RETURN
700 PRINT "GO WEST" :RETURN
```

```
800 PRINT "GO NORTHWEST":RETURN
```

OPEN

Token: \$9F

Format: **OPEN lfn, first address [,secondary address [,filename]]**

Usage: Opens an input/output channel for a device.

lfn = logical file number

1 <= lfn <= 127: line terminator is CR

128 <= lfn <= 255: line terminator is CR LF

first address = device number. For IEC devices the unit number is the primary address. Following primary address values are possible:

unit	device
0	Keyboard
1	System default
2	RS232 serial connection
3	Screen
4-7	IEC printer and plotter
8-31	IEC disk drives

The **secondary address** has some special values for IEC disk units, 0:load, 1:save, 15:command channel. The values 2 -> 14 may be used for disk files.

filename is either a quoted string, e.g. **"data"** or a string expression. The syntax is different to the **DOPEN#** command. The **filename** for **OPEN** includes all file attributes, e.g.: "0:data,s,w".

Remarks: For IEC disk units the usage of **DOPEN#** is recommended.

The usage of the "save-and-replace" character 'a' at the beginning of the filename is not recommended, because many Commodore disk drives have a bug, that can cause data loss when using this feature.

Example: Using **OPEN**

```
OPEN 4,4 :REM OPEN PRINTER
CMD 4 :REM REDIRECT STANDARD OUTPUT TO 4
LIST :REM PRINT LISTING ON PRINTER DEVICE 4
OPEN 3,0,3,"0:USER FILE,U"
OPEN 2,9,2,"0:DATA,S,W"
```

OR

Token: \$B0

Format: operand **OR** operand

Usage: Performs a bitwise logical OR operation on two 16-bit values. Integer operands are used as they are. Real operands are converted to a signed 16-bit integer. Logical operands are converted to 16-bit integer using \$FFFF, decimal -1 for TRUE and \$0000, decimal 0, for FALSE.

```
0 OR 0  -> 0
0 OR 1  -> 1
1 OR 0  -> 1
1 OR 1  -> 1
```

Remarks: The result is of integer type. If the result is used in a logical context, the value of 0 is regarded as FALSE, all other, nonzero values are regarded as TRUE.

Example: Using **OR**

```
PRINT 1 OR 3
3
PRINT 128 OR 64
192
```

In most cases the **OR** will be used in **IF** statements.

```
IF (C < 0 OR C > 255) THEN PRINT "NOT A BYTE VALUE"
```

PAINT

Token: \$DF

Format: **PAINT** *x, y, mode* [*,colour*]

Usage: Performs a flood fill of an enclosed graphics area.

x, y is a coordinate pair, which must lie inside the area to be filled.

mode specifies the fill mode.

0: use the **colour** to fill the area.

1: use the colour of pixel (x,y) to fill the area.

Example: Using **PAINT**

```
10 GRAPHIC CLR          :REM INITIALIZE
20 SCREEN DEF 1,0,0,2    :REM 320 X 200
30 SCREEN OPEN 1         :REM OPEN
40 SCREEN SET 1,1        :REM MAKE SCREEN ACTIVE
50 LINE 160,0,240,100    :REM 1ST. LINE
60 LINE 240,100,80,100   :REM 2ND. LINE
70 LINE 80,100,160,0     :REM 3RD. LINE
80 PAINT 160,10,0,1      :REM FILL TRIANGLE WITH COLOUR 1
90 GETKEY K$             :REM WAIT FOR KEY
100 SCREEN CLOSE 1       :REM END GRAPHICS
```

PALETTE

Token: \$FE \$34

Format: **PALETTE** [**screen**|**COLOR**], **colour**, **red**, **green**, **blue**
PALETTE RESTORE

Usage: The **PALETTE** command can be used to change an entry of the system colour palette or the palette of a screen.
PALETTE RESTORE resets the system palette to the default values.

screen = screen number (0 or 1).

COLOR = keyword for changing system palette.

colour = index to palette 0 -> 255.

red = red intensity 0 -> 15.

green = green intensity 0 -> 15.

blue = blue intensity 0 -> 15.

Example: Using **PALETTE**

```
10 GRAPHIC CLR           :REM INITIALIZE
20 SCREEN DEF 1,0,0,2    :REM 320 X 200
30 SCREEN OPEN 1         :REM OPEN
40 SCREEN SET 1,1        :REM MAKE SCREEN ACTIVE
50 PALETTE 1,0, 0, 0, 0  :REM 0 = BLACK
60 PALETTE 1,1, 15, 0, 0 :REM 1 = RED
70 PALETTE 1,2, 0, 0,15  :REM 2 = BLUE
80 PALETTE 1,3, 0,15, 0  :REM 3 = GREEN
90 LINE 160,0,240,100    :REM 1ST. LINE
100 LINE 240,100,80,100  :REM 2ND. LINE
110 LINE 80,100,160,0     :REM 3RD. LINE
120 PAINT 160,10,0,2     :REM FILL TRIANGLE WITH BLUE (2)
130 GETKEY K$            :REM WAIT FOR KEY
140 SCREEN CLOSE 1       :REM END GRAPHICS
```

PEEK

Token: \$C2

Format: PEEK(address)

Usage: Returns a byte value read from the 16 bit address and the current memory bank (set by **BANK**).

address = a value 0 -> 65535.

Remarks: Banks 0 -> 127 give access to RAM or ROM banks. Banks > 127 are used to access I/O and SYSTEM like VIC, SID, FDC, etc.

Example: Using **PEEK**

```
10 BANK 128           :REM SELECT SYSTEM BANK
20 L = PEEK(DEC("02F8")) :REM USR JUMP TARGET LOW
30 H = PEEK(DEC("02F9")) :REM USR JUMP TARGET HIGH
40 T = L + 256 * H      :REM 16 BIT JUMP ADDRESS
50 PRINT "USR FUNCTION CALLS ADDRESS";T
```

PEN

Token: \$FE \$33

Format: **PEN** pen colour

Usage: Sets the colour for the graphic pen.

pen = pen number (0 -> 2)

colour = palette index.

Remarks: **PEN** defined colours are used by all following drawing commands.

Example: Using **PEN**

```
10 GRAPHIC CLR           :REM INITIALIZE
20 SCREEN DEF 1,0,0,2    :REM 320 X 200
30 SCREEN OPEN 1         :REM OPEN
40 SCREEN SET 1,1        :REM MAKE SCREEN ACTIVE
50 PALETTE 1,0, 0, 0, 0  :REM 0 = BLACK
60 PALETTE 1,1, 15, 0, 0 :REM 1 = RED
70 PALETTE 1,2, 0, 0,15  :REM 2 = BLUE
80 PALETTE 1,3, 0,15, 0  :REM 3 = GREEN
90 PEN 0,1               :REM PEN 0 = RED
100 LINE 160,0,240,100   :REM DRAW RED LINE
110 PEN 0,2              :REM PEN 0 = BLUE
120 LINE 240,100,80,100  :REM DRAW BLUE LINE
130 PEN 0,3              :REM PEN 0 = GREEN
140 LINE 80,100,160,0    :REM DRAW GREEN LINE
150 GETKEY K$            :REM WAIT FOR KEY
160 SCREEN CLOSE 1       :REM END GRAPHICS
```

PLAY

Token: \$FE \$04

Format: **PLAY string**

Usage: Starts playing a tune with notes and directives embedded in the argument string.

A musical note is a letter (A,B,C,D,E,F,G) which may be preceded by an optional modifier.

Possible modifiers are:

char	effect
#	sharp
\$	flat
.	dotted
H	half note
I	eighth note
M	wait for end
Q	quarter note
R	pause (rest)
S	sixteenth note
W	whole note

Embedded directives consist of a letter followed by a digit:

char	directive	argument range
0	octave	0 - 6
T	tune envelope	0 - 9
U	volume	0 - 9
V	voice	1 - 3
X	filter	0 - 1

The envelope slots may be changed using the **ENVELOPE** statement. The default setting for the envelopes are:

n	A	D	S	R	WF	PW	Instrument
0	0	9	0	0	2	1536	piano
1	12	0	12	0	1		accordion
2	0	0	15	0	0		calliope
3	0	5	5	0	3		drum
4	9	4	4	0	0		flute
5	0	9	2	1	1		guitar
6	0	9	0	0	2	512	harpsichord
7	0	9	9	0	2	2048	organ
8	8	9	4	1	2	512	trumpet
9	0	9	0	0	0		xylophone

Remarks: The **PLAY** statement sets up an interrupt driven routine that starts parsing the string and playing the tune. The execution continues with the next statement with no need waiting for the tune to be finished. However this can be forced, using the 'M' modifier.

Example: Using **PLAY**

```
10 ENVELOPE 9,10,5,10,5,2,4000
20 PLAY "T9"
30 VOL 8
40 TEMPO 100
50 PLAY "C D E F G A B"
60 PLAY "U5 V1 C D E F G A B"
```

POINTER

Token: \$CE \$0A

Format: **POINTER**(variable)

Usage: Returns the current address of a variable or an array element in bank 1. For string variables, it is the address of the string descriptor, not the string itself. The string descriptor consists of the three bytes (length,string address low, string address high).

Remarks: The address values of arrays and their elements change for every new declaration (first usage) of scalar variables. The addresses of strings (not their descriptors) may change at any time due to "garbage collection" in memory management.

Example: Using **POINTER**

```
10 A$="TEXT": B%=5: DIM C(100) :REM DEFINE SOME VARIABLES
20 PRINT POINTER(A$);POINTER(B%);POINTER(C(20))

1026 1033 1145
```

POKE

Token: \$97

Format: **POKE address, byte [,byte ...]**

Usage: Puts on or more bytes into memory or memory mapped I/O, starting at 16-bit **address**. The current memory bank as set by **BANK** is used.

address = a value 0 -> 65535.

byte = a value 0 -> 255.

Remarks: The address is increased by one for each data byte, so a memory range may be filled with a single command.

Banks > 127 are used to access I/O and SYSTEM like VIC, SID, FDC, etc.

Example: Using **POKE**

```
10 BANK 128 :REM SELECT SYSTEM BANK
20 POKE,DEC("02F8"),0,32 :REM SET USR VECTOR TO $2000
```

POLYGON

Token: \$FE \$2F

Format: **POLYGON** **x, y, xrad, yrad, solid, angle, sides, n**

Usage: Draws a regular **n** sided polygon. The polygon is drawn using the current drawing context set with SCREEN, PALETTE and PEN.

x,y = centre coordinates.

xrad,yrad = radius in x- and y-direction.

solid = fill (1) or outline (0).

angle = start angle.

sides = sides to draw ($\leq n$).

n = number of sides or edges.

Remarks: A regular polygon is both isogonal and isotoxal, meaning all sides and angles are alike.

Example: Using **POLYGON**

```
POLYGON 320,100,50,50,0,0,6,6
```

POS

Token: \$B9

Format: **POS(dummy)**

Usage: Returns the cursor column relative to the currently used window.
dummy = a numeric value, which is ignored.

Remarks: **POS** gives the column position for the screen cursor. It will not work for redirected output.

Example: Using **POS**

```
10 IF POS(0) > 72 THEN PRINT :REM INSERT RETURN
```

POT

Token: \$CE \$02

Format: POT(paddle)

Usage: Returns the position of a paddle.

paddle = paddle number 1 -> 4.

The low byte of the return value is the paddle value with 0 at the clockwise limit and 255 at the counterclockwise limit.

A value > 255 indicates the simultaneous press of the firebutton.

Remarks: Analogue paddles are noisy and inexact. The range may be less than 0 - 255 and there is some jitter in the data.

Example: Using **POT**

```
10 X = POT(1)      : REM READ PADDLE #1
20 B = X > 255      : REM TRUE (-1) IF FIRE BUTTON IS PRESSED
30 V = X AND 255    : PADDLE #1 VALUE
```

PRINT

Token: \$99

Format: **PRINT arguments**

Usage: Evaluates the argument list and prints the values formatted to the current screen window. Standard formatting is used dependent on the argument type. For user controlled formatting see **PRINT USING**. Following argument types are processed:

numeric : The printout starts with a space for positive and zero values or a minus sign for negative values. Integer values are printed with the necessary number of digits. Real values are printed either in fixed point format with typically 9 digits or in scientific format, if the value is outside the range of 0.01 -> 999999999.

string : The string may consist of printable characters and control codes. Printable characters are printed to the cursor position, while control codes are executed.

, : A comma acts like a tabulator.

; : A semicolon acts as a separator between arguments of the list. Other than the comma character it does not put in any additional characters. A semicolon at the end of the argument list suppresses the automatic return character.

Remarks: The **SPC** and **TAB** functions may be used in the argument list for positioning. The **CMD** command can be used for redirection.

Example: Using **PRINT**

```
10 FOR I=1 TO 10 : REM START LOOP
20 PRINT I,I*I,SQR(I)
30 NEXT
```

PRINT#

Token: \$98

Format: **PRINT# channel, arguments**

Usage: Evaluates the argument list and prints the values formatted to the device assigned to **channel**. Standard formatting is used dependent on the argument type. For user controlled formatting see **PRINT# USING**. Following argument types are processed:

channel : must be opened for output by an **OPEN** or **DOPEN** statement.

numeric : The printout starts with a space for positive and zero values or a minus sign for negative values. Integer values are printed with the necessary number of digits. Real values are printed either in fixed point format with typically 9 digits or in scientific format, if the value is outside the range of 0.01 -> 9999999999.

string : The string may consist of printable characters and control codes. Printable characters are printed to the cursor position, while control codes are executed.

, : A comma acts like a tabulator.

; : A semicolon acts as a separator between arguments of the list. Other than the comma character it does not put in any additional characters. A semicolon at the end of the argument list suppresses the automatic return character.

Remarks: The **SPC** and **TAB** functions are not suitable for devices other than the screen.

Example: Using **PRINT#**

```
10 DOPEN#2,"TABLE",W,U9
20 FOR I=1 TO 10 : REM START LOOP
30 PRINT#2,I,I*I,SQR(I)
40 NEXT
50 DCLOSE#2
```

PRINT USING

Token: \$98 \$FB or \$99 \$FB

Format: **PRINT [# channel,] USING, format, arguments**

Usage: Parses the format string and evaluates the argument list. The values are printed following the directives of the format string.

channel : must be opened for output by an **OPEN** or **DOPEN** statement. If no channel is specified, the output goes to the screen.

format : A string which defines the rules for formatting.

numeric argument : The '#' characters set the position and width of the output string.

'+' or '-' set the sign option.

'.' sets the position of the decimal point.

'/' can be inserted into large numbers.

'\$' sets the position of the currency symbol.

^^^^ reserves place for the exponent.

string argument : The string may consist of printable characters and control codes. Printable characters are printed to the cursor position, while control codes are executed. The number of '#' characters sets the width of the output, a '=' sign centers and a '>' character right justifies the output.

, : A comma acts like a tabulator. ; : A semicolon acts as a separator between arguments of the list. Other than the comma character it does not put in any additional characters. A semicolon at the end of the argument list suppresses the automatic return character.

Remarks: The **SPC** and **TAB** functions may be used for screen output.

Example: Using **PRINT# USING**

```
10 X = 12.34: A$ = "MEGA 65"
30 PRINT USING "###.##"; X      : REM "12.34"
40 PRINT USING "###"; X        : REM " 12"
50 PRINT USING "####"; A$      : REM "MEGA"
60 PRINT USING "#####"; A$    : REM "MEGA 65 "
70 PRINT USING "=#####"; A$   : REM " MEGA 65 "
80 PRINT USING "#####>#"; A$  : REM "  MEGA 65"
```

PUDEF

Token: \$DD

Format: **PUDEF** string

Usage: Redefines up to four special characters, that are used in the **PRINT USING** routine.

string = definition string (max. 4 characters).

1st.: fill character
2nd.: comma separator
3rd.: decimal point
4th.: currency symbol

The system default is " ,. \$"

The new definition string overrides the system default and is often used for localization. A string " .," would change the punctuation to German style.

It is not necessary to redefine all four characters. Any length between 1 and 4 is allowed.

Remarks: **PUDEF** changes the output of **PRINT USING** only. **PRINT** and **PRINT#** are not affected. The control characters of the format string cannot be changed.

Example: Using **PUDEF**

```
10 X = 123456.78
20 PUDEF " ,,"
30 PRINT USING "####,###.##"; X : REM 123.456,8
```

RCLR

Token: \$CD

Format: **RCLR(colour source)**

Usage: Returns the current colour index for the selected colour source.

Colour sources are:

- 0: 40 column background
- 1: graphical foreground
- 2: multicolour mode 1
- 3: multicolour mode 2
- 4: frame colour
- 5: 80 column text
- 6: 80 column background

Example: Using **RCLR**

```
10 C = RCLR(5) : REM C = colour index of 80 column text
```

RDOT

Token: \$D0

Format: RDOT(n)

Usage: Returns information about the graphical cursor.

n = kind of information.

0: x-position

1: y-position

2: colour index

Example: Using **RDOT**

```
10 X = RDOT(0)
20 Y = RDOT(1)
30 C = RDOT(2)
40 PRINT "THE COLOUR INDEX AT (\";X;\"/\";Y;) IS: ";C
```

READ

Token: \$87

Format: **READ(variable list)**

Usage: Reads values from program source into variables.

variable list = any legal variables.

All type of constants (integer, real, strings) can be read, but no expressions. Items are separated by commas. Strings containing commas, colons or spaces must be put in quotes.

A **RUN** command initializes the data pointer to the first item of the first **DATA** statement and advances it for every read item. It is in the responsibility of the programmer, that the type of the constant and the variable in the **READ** statement match. Empty items with no constant between commas are allowed and will be interpreted as zero for numeric variables and an empty string for string variables.

The **RESTORE** command may be used to set the data pointer to a specific line for subsequent readings.

Remarks: It is good programming style to put large amount of **DATA** statements at the end of the program. Otherwise **GOTO** and **GO-SUB** statements, with target lines lower than the current one, start their search for linenumber at the beginning of the program and have to skip through **DATA** lines wasting time.

Example: Using **READ**

```
10 READ NA$, VE
20 READ NX:FOR I=2 TO NX:READ GL(I):NEXT I
30 PRINT "PROGRAM: ";NA$,"  VERSION: ";VE
40 PRINT "N-POINT GAUSS-LEGENDRE FACTORS E1":
50 FOR I=2 TO NX:PRINT I;GL(I):NEXT I
30 STOP
80 DATA "MEGA 65",1.1
90 DATA 5,0.5120,0.3573,0.2760,0.2252
```

RECORD

Token: \$FE \$12

Format: **RECORD**#lfn, record, [,byte]

Usage: Positions the read/write pointer of a relative file.

lfn = logical file number

record = target record (1 -> 65535).

byte = byte position in record.

This command can be used only for files of type **REL**, which are relative files capable of direct access.

The **RECORD** command positions the file pointer to the specified record number. If this record number does not exist and the disk capacity is high enough, the file is expanded to this record count by adding empty records. This is not an error, but the disk status will give the message **RECORD NOT PRESENT**.

Any **INPUT#** or **PRINT#** command will then proceed on the selected record position.

Remarks: The original Commodore disk drives all had a bug in their DOS, which could destroy data by using relative files. A recommended workaround was to issue each **RECORD** command twice, before and after the I/O operation.

Example: Using **RECORD**

```
10 REM *** READ FIRST 10 INDEXED RECORDS FROM DATA BASE
15 N = 1000: DIM IX(N)
20 DOPEN#3,"DATA INDX"
25 FOR I=1 TO N:INPUT#3,IX(I):NEXT
30 DCLOSE#3
35 DOPEN#2,"DATA BASE",L240
40 FOR J=1 TO 10
45 RECORD#2,IX(J)
50 INPUT#2,A$
55 PRINT A$
60 NEXT J
65 DCLOSE#2
```

REM

Token: \$8F

Format: **REM**

Usage: Marks the rest of the line as comment.

All characters after **REM** are never executed but skipped.

Example: Using **REM**

```
10 REM *** PROGRAM TITLE ***  
20 N=1000 :REM NUMBER OF ITEMS  
30 DIM NA$(N)
```

RENAME

Token: \$F5

Format: **RENAME** old **TO** new [,D drive] [,U unit]

Usage: Renames a disk file.

old is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**.

new is either a quoted string, e.g. **"backup"** or a string expression in parentheses, e.g. **(F\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: The **RENAME** command is executed in the DOS of the disk drive. It can rename all regular file types (PRG, SEQ, USR, REL). The old file must exist, the new file must not exist. Only single files can be renamed, wild characters like '*' and '?' are not allowed. The file type cannot be changed.

Example: Using **RENAME**

```
RENAME "CODES" TO "BACKUP" :REM RENAME SINGLE FILE
```

RENUMBER

Token: \$F8

Format: **RENUMBER** [**new**, **inc**, **old**]

Usage: Used to renumber all or a range of lines of a BASIC program.

new is the new starting line of the line range to renumber. The default value is 10.

inc is the increment to be used. The default value is 10.

old is the old starting line of the line range to renumber. The default value is the first line.

The **RENUMBER** changes all line numebrs in the chosen range and also changes all references from statements like **GOTO**, **GOSUB**, **TRAP**, **RESTORE**, **RUN** etc.

RENUMBER can be executed in direct mode only. If it detects a problem, like memory overflow, unresolved references or line number overflow (greater than 64000) it will stop with an error message and leave the program unchanged.

The command may be called with 0-3 parameters. Unspecified parameters use their default values.

Remarks: The **RENUMBER** command may need several minutes to execute for large programs.

Example: Using **RENUMBER**

```
RENUMBER           :REM NUMBERS WILL BE 10,20,30,...  
RENUMBER 100,5     :REM NUMBERS WILL BE 100,105,110,115,...  
RENUMBER 601,1,500 :REM RENUMBER STARTING AT 500 TO 601,602,...
```

RESTORE

Token: \$8C

Format: **RESTORE** [**line**]

Usage: Set or reset the internal pointer for **READ** from **DATA** statements.

line is the new position for the pointer to point at. The default is the first program line.

Remarks: The new pointer target **line** needs not to contain **DATA** statements. Every **READ** will automatically advance the pointer to the next **DATA** statement.

Example: Using **RESTORE**

```
10 DATA 3,1,4,1,5,9,2,6
20 DATA "MEGA 65"
30 DATA 2,7,1,8,2,8,9,5
40 FOR I=1 TO 8:READ P:PRINT P:NEXT
50 RESTORE 30
60 FOR I=1 TO 8:READ P:PRINT P:NEXT
70 RESTORE 20
80 READ A$:PRINT A$
```

RESUME

Token: \$D6

Format: **RESUME** [**line** | **NEXT**]

Usage: is used inside a **TRAP** routine to resume normal program execution after handling the exception.

line : program execution resumes at the given line number.

NEXT : the keyword **NEXT** resumes execution at the statement following the statement, that caused the error.

RESUME with no parameters tries to re-execute the statement, that caused the error. The **TRAP** routine should have examined and corrected the variables in this case.

Remarks: **RESUME** cannot be used in direct mode.

Example: Using **RESUME**

```
10 TRAP 100
20 FOR I=1 TO 100
30 PRINT EXP(I)
40 NEXT
50 PRINT "STOPPED FOR I =";I
60 END
100 PRINT ERR$(ER): RESUME 50
```

RETURN

Token: \$8E

Format: **RETURN**

Usage: Returns control from a subroutine, which was called with **GOSUB** or an event handler, declared with **COLLISION**.

The execution continues at the statement following the **GOSUB** call.

In the case of the **COLLISION** handler, the execution continues at the statement where it left to call the handler.

Example: Using **RETURN**

```
10 DOPEN#2,"DATA":GOSUB 100
20 FOR I=1 TO 100
30 INPUT#2,A$:GOSUB 100
40 PRINT A$
50 NEXT
60 DCLOSE#2
70 END
100 IF DS THEN PRINT D$$:STOP :REM DISK ERROR
110 RETURN :REM OK
```

RGR

Token: \$CC

Format: **RGR(dummy)**

Usage: Returns information about the graphic mode.

dummy = unused numeric expression.

In text mode **RGR** returns zero. in graphics mode **RGR** returns a non zero value.

Example: Using **RGR**

```
10 M = RGR(0)
20 IF M THEN CHAR 0,0,1,1,2,"TITLE": ELSE PRINT "TITLE"
```

RIGHT\$

Token: \$C9

Format: RIGHT\$(string, n)

Usage: Returns a string containing the last **n** characters from the argument **string**. If the length of **string** is equal or less than **n**, the result string will be identical to the argument string.

string = a string expression

n = a numeric expression (0 -> 255)

Remarks: Empty strings and zero lengths are legal values.

Example: Using RIGHT\$:

```
PRINT RIGHT$("MEGA-65",2)
65
```

RMOUSE

Token: \$FE \$3F

Format: **RMOUSE** *xvar*, *yvar*, *butvar*

Usage: Reads mouse position and button status.

xvar = numerical variable receiving x-position.

yvar = numerical variable receiving y-position.

butvar = numerical variable receiving button status.
left button sets bit 7, while right button sets bit 0.

value	status
0	no button
1	right button
128	left button
129	both buttons

The command puts a -1 into all variables, if the mouse is not connected or disabled.

Remarks: Two active mice on both ports merge the results.

Example: Using **RMOUSE**:

```
10 MOUSE ON, 1, 1      :REM MOUSE ON PORT 1 WITH SPRITE 1
20 RMOUSE XP, YP, BU    :REM READ MOUSE STATUS
30 IF XP < 0 THEN PRINT "NO MOUSE ON PORT 1":STOP
40 PRINT "MOUSE: ";XP;YP;BU
50 MOUSE OFF           :REM DISABLE MOUSE
```

RND

Token: \$BB

Format: RND(**type**)

Usage: Returns a pseudo random number

This is called a "pseudo" random number, because the numbers are not really random, but are derived from another number called "seed" and generate reproducible sequences. The **type** argument determines, which seed is used.

type = 0: use system clock.

type < 0: use the value of **type** as seed.

type > 0: derive value from previous random number.

Remarks: Seeded random number sequences produce the same sequence for identical seeds.

Example: Using RND:

```
10 DEF FNDI(X) = INT(RND(0)*6)+1 :REM DICE FUNCTION
20 FOR I=1 TO 10                :REM THROW 10 TIMES
30 PRINT I;FNDI(0)              :REM PRINT DICE POINTS
40 NEXT
```

RREG

Token: \$FE \$09

Format: **RREG** *areg, xreg, yreg, zreg, sreg*

Usage: Reads the values, that were in the CPU registers after a SYS call, into the specified variables.

areg = variable gets accumulator value.

xreg = variable gets X register value.

yreg = variable gets Y register value.

zreg = variable gets Z register value.

sreg = variable gets status register value.

Remarks: The register values after a SYS call are stored in system memory. This enables the command **RREG** to retrieve these values.

Example: Using **RREG**:

```
10 BANK 128
20 BLOAD "ML PROG",8192
30 SYS 8192
40 RREG A,X,Y,Z,S
50 PRINT "REGISTER: ";A;X;Y;Z;S
```

RSPCOLOR

Token: \$CE \$07

Format: RSPCOLOR(n)

Usage: Returns multicolour sprite colours.

n = 1 : get multicolour # 1.

n = 2 : get multicolour # 2.

Remarks: See also **SPRITE** and **SPRCOLOR**.

Example: Using **RSPCOLOR**:

```
10 SPRITE 1,1      :REM TURN SPRITE 1 ON
20 C1% = RSPCOLOR(1) :REM READ COLOUR #1
30 C2% = RSPCOLOR(2) :REM READ COLOUR #2
```

RSPPOS

Token: \$CE \$05

Format: RSPPOS(sprite,n)

Usage: Returns sprite's position and speed

sprite : sprite number.

n = 0 : get X position.

n = 1 : get Y position.

n = 2 : get speed.

Remarks: See also **SPRITE** and **MOVSPR**.

Example: Using **RSPPOS**:

```
10 SPRITE 1,1      :REM TURN SPRITE 1 ON
20 XP = RSPPOS(1,0) :REM GET X OF SPRITE 1
30 YP = RSPPOS(1,1) :REM GET Y OF SPRITE 1
30 SP = RSPPOS(1,2) :REM GET SPEED OF SPRITE 1
```

RSPRITE

Token: \$CE \$06

Format: RSPRITE(sprite,n)

Usage: Returns sprite's parameter.

sprite : sprite number (0 -> 7)

n = 0 : turned on (0 or 1).

n = 1 : foreground colour (0 -> 15)

n = 2 : background priority (0 or 1).

n = 3 : X-expanded (0 or 1).

n = 4 : Y-expanded (0 or 1).

n = 5 : multicolour (0 or 1).

Remarks: See also **SPRITE** and **MOVSPR**.

Example: Using **RSPRITE**:

```
10 SPRITE 1,1      :REM TURN SPRITE 1 ON
20 EN = RSPRITE(1,0) :REM SPRITE 1 ENABLED ?
30 FG = RSPRITE(1,1) :REM SPRITE 1 FOREGROUND COLOUR INDEX
30 BP = RSPRITE(1,2) :REM SPRITE 1 BACKGROUND PRIORITY
20 XE = RSPRITE(1,3) :REM SPRITE 1 X EXPANDED ?
30 YE = RSPRITE(1,4) :REM SPRITE 1 Y EXPANDED ?
30 MC = RSPRITE(1,5) :REM SPRITE 1 MULTICOLOUR ?
```

RUN

Token: \$8A

Format: **RUN** [line number]
RUN filename [,D drive] [,U unit]

Usage: Run a BASIC program.

If a filename is given, the program file is loaded into memory, otherwise the program that is currently in memory is used.

line number an existing line number of the program in memory.

filename is either a quoted string, e.g. "**prog**" or a string expression in parentheses, e.g. (**PR\$**). The filetype must be "PRG".

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

RUN resets first all internal pointers to their starting values. Therefore there are no variables, arrays and strings defined, the runtime stack is reset and the table of open files is cleared.

Remarks: In order to start or continue program execution without resetting everything, use the **GOTO** command.

Example: Using **RUN**

```
RUN "FLIGHTSIM" :LOAD AND RUN PROGRAM FLIGHTSIM
RUN 1000       :RUN PROGRAM IN MEMORY, START AT 1000
RUN           :RUN PROGRAM IN MEMORY
```

SAVE

Token: \$94

Format: **SAVE filename [,unit]**

Usage: "Saves a BASIC program to a file of type PRG.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FNS)** The maximum length of the filename is 16 characters, not counting the optional save and replace character 'e' and the infile drive definition.. If the first character of the filename is an at-sign 'e' it is interpreted as a "save and replace" operation. It is dangerous to use this replace option on drives 1541 and 1571, because they contain the notorious "save and replace bug" in their DOS. The filename may be preceded by the drive number definition "0:" or "1:" which is only relevant for dual drive disk units.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: This is an obsolete command, implemented only for compatibility to older BASIC dialects. The command **DSAVE** should be used instead.

Example: Using **SAVE**

```
SAVE "ADVENTURE"  
SAVE "ZORK-I",8  
SAVE "1:DUNGEON",9
```

SCNCLR

Token: \$E8

Format: **SCNCLR** [colour]

Usage: Clears a text window or screen.

SCNCLR (with no arguments) clears the current text window. The default window occupies the whole screen.

SCNCLR colour clears the graphic screen by filling it with the **colour**.

Example: Using **SCNCLR**:

```
10 GRAPHIC CLR      :REM INITIALIZE
20 SCREEN DEF 1,1,1,2 :REM 640 X 400 X 2
30 SCREEN SET 1,1    :REM VIEW IT
40 SCNCLR 0          :REM CLEAR SCREEN
50 LINE 50,50,590,350 :REM DRAW LINE
```

SCRATCH

Token: \$F2

Format: **SCRATCH filename [,D drive] [,U unit] [,R]**

Usage: Used to erase a disk file.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

R = Recover a previously erased file. This will only work, if there were no write operations between erasion and recovery, which may have altered the contents of the file.

Remarks: The **SCRATCH filename** command works like the **ERASE filename** command.

The success and the number of erased files can be examined by printing or using the system variable DS\$. The second last number, which reports the track number in case of an disk error, now reports the number of successfully erased files.

Example: Using **SCRATCH**

```
SCRATCH "DRM",U9 :REM SCRATCH FILE DRM ON UNIT 9
PRINT DS$
01, FILES SCRATCHED,01,00
SCRATCH "OLD*" :REM SCRATCH ALL FILES BEGINNING WITH "OLD"
PRINT DS$
01, FILES SCRATCHED,04,00
```

SCREEN

Token: \$FE \$2E

Format: **SCREEN CLR**
SCREEN DEF
SCREEN SET
SCREEN OPEN screen [,errvar]
SCREEN CLOSE screen

Usage: **SCREEN** performs one of five actions, selected by the secondary keyword after it.

SCREEN CLR colour clear graphics screen by filling it with colour.

SCREEN DEF screen, width, height, depth defines resolution parameters for the chosen screen.

SCREEN SET draw view sets screen numbers (0 or 1) for the drawing and the viewing screen.

SCREEN OPEN screen allocates resources and initializes the graphic context for the selected screen (0 or 1). An optional variable name as a further argument, gets the result of the command and can be tested afterwards for success.

SCREEN CLOSE screen closes screen (0 or 1) and frees resources.

Remarks: The **SCREEN** command cannot be used alone. It must always be used together with a secondary keyword.

Example: Using **SCREEN**:

```
10 GRAPHIC CLR      :REM INITIALIZE
20 SCREEN DEF 1,0,0,2 :REM SCREEN #1: 320 X 200 X 2
30 SCREEN OPEN 1    :REM OPEN SCREEN 1
40 SCREEN SET 1,1    :REM USE SCREEN 1 FOR RENDERING AND VIEWING
50 SCREEN CLR 0      :REM CLEAR SCREEN
60 LINE 25,25,295,175 :REM DRAW LINE
70 SLEEP 10         :REM WAIT 10 SECONDS
80 SCREEN CLOSE 1    :REM CLOSE SCREEN 1
```

SET

Token: \$FE \$2D

Format: **SET DEF unit**
SET DISK old to new

Usage: **SET DEF unit** redefines the default unit for disk access, which is initialized to 8 by the DOS. Commands, that do not explicitly specify a unit, will use this default unit.

SET DISK old to new is used to change the unit number of a disk drive temporarily.

Remarks: These settings are valid until a reset or shutdown.

Example: Using **SET**:

```
DIR          :REM SHOW DIRECTORY OF UNIT 8
SET DEF 11   :REM UNIT 11 BECOMES DEFAULT
DIR          :REM SHOW DIRECTORY OF UNIT 11
DLOAD "*"    :REM LOAD FIRST FILE FROM UNIT 11
SET DISK 8 TO 9 :REM CHANGE UNIT# OF DISK DRIVE 8 TO 9
DIR U9       :REM SHOW DIRECTORY OF UNIT 9 (FORMER 8)
```

SGN

Token: \$B4

Format: **SGN**(numeric expression)

Usage: The **SGN** function extracts the sign from the argument and returns it as a number:

-1 for a negative argument

0 for a zero

1 for a positive, non zero argument

Example: Using **SGN**

```
10 ON SGN(X)+2 GOTO 100,200,300 :REM TARGETS FOR MINUS,ZERO,PLUS  
20 Z = SGN(X) * ABS(Y) : REM COMBINE SIGN OF X WITH VALUE OF Y
```

SIN

Token: \$BE

Format: **SIN**(numeric expression)

Usage: The **SIN** function returns the sine of the argument. The argument is expected in units of **[radians]**. The result is in the range (-1.0 to +1.0)

Remarks: An argument in units of **[degrees]** can be converted to **[radians]** by multiplication with $\pi/180$.

Example: Using **SIN**

```
PRINT SIN(0.7)
.644217687

X=30:PRINT SIN(X *  $\pi$  / 180)
.5
```

SLEEP

Token: \$FE \$0B

Format: **SLEEP** seconds

Usage: The **SLEEP** commands pauses the execution for the given duration (1 - 65535).

Example: Using **SLEEP**

```
50 GOSUB 1000 :REM DISPLAY SPLASH SCREEN
60 SLEEP 10 :REM WAIT 10 SECONDS
70 GOTO 2000 :REM START PROGRAM
```

SLOW

Token: \$FE \$26

Format: **SLOW**

Usage: Slow down system clock to 1 MHz.

Example: Using **SLOW**

```
50 SLOW      :REM SET SPEED TO MINIMUM  
60 GOSUB 100 :REM EXECUTE SUBROUTINE AT 1 MHZ  
70 FAST      :REM BACK TO HIGH SPEED
```

SOUND

Token: \$DA

Format: **SOUND** voice, freq, dur [,dir ,min, sweep, wave, pulse]

Usage: plays a sound effect.

voice = voice number (1 -> 6).

freq = frequency (0 -> 65535).

dur = duration (0 -> 32767).

dir = direction (0:up, 1:down, 2:oscillate).

min = minimum frequency (0 -> 65535).

sweep = sweep range (0 -> 65535).

wave = waveform (0:triangle, 1:saw, 2:square, 3:noise).

pulse = pulse width (0 -> 5095).

For details on sound programming, read the **SOUND** chapter.

Remarks: The **SOUND** command starts playing the sound effect and immediately continues with the execution of the next BASIC statement, while the sound effect is played. This enables showing graphics or text and playing sounds simultaneously.

Example: Using **SOUND**

```
SOUND 1, 7382, 60 :REM PLAY SQUARE WAVE ON VOICE 1 FOR 1 SECOND
SOUND 2, 800, 3600 :REM PLAY SQUARE WAVE ON VOICE 2 FOR 1 MINUTE
SOUND 3, 4000, 120, 2, 2000, 400, 1
REM PLAY SWEEPING SAWTOOTH WAVE AT VOICE 3
```

SPC

Token: \$A6

Format: **SPC(columns)**

Usage: The **SPC** function skips **columns**.
The effect is like printing **column** times a **cursor right character**.

Remarks: The name of this function is derived from **SPACES**, which is misleading. The function prints **cursor right characters** not **SPACES**. The contents of those character cells, that are skipped, will not be changed.

Example: Using **SPC**

```
10 FOR I=8 TO 12
20 PRINT SPC(-(I<10));I :REM TRUE = -1, FALSE = 0
30 NEXT I
RUN
 8
 9
10
11
12
```

SPRCOLOR

Token: \$FE \$08

Format: **SPRCOLOR** [**mc1**] [,**mc2**]

Usage: Sets multicolour sprite colours.
The **SPRITE** command, which sets the attributes of a sprite, sets only the foreground colour. For the setting of the additional two colours, of multicolour sprites, **SPRCOLOR** has to be used.

Remarks: See also **SPRITE**.

Example: Using **SPRCOLOR**:

```
10 SPRITE 1,1,2,,,,1 :REM TURN SPRITE 1 ON (FG = 2)
20 SPRCOLOR 4,5      :REM MC1 = 4, MC2 = 5
```

SPRITE

Token: \$FE \$07

Format: **SPRITE** **no** [**switch**, **colour**, **prio**, **expx**, **expy**, **mode**]

Usage: Switches a sprite on or off and sets its attributes.

no = sprite number

switch = 1:ON, 0:OFF

colour = sprite foreground colour

prio = sprite(1) or screen(0) priority

expx = 1:sprite X expansion

expy = 1:sprite Y expansion

mode = 1:multi colour sprite

Remarks: The command **SPRCOLOR** must be used to set additional colours for multi colour sprites (mode = 1)

Example: Using **SPRITE**:

```
10 COLLISION 1,70 : REM ENABLE
20 SPRITE 1,1 : MOVSPR 1,120, 0 : MOVSPR 1,0#5
30 SPRITE 2,1 : MOVSPR 2,120,100 : MOVSPR 2,180#5
40 FOR I=1 TO 50000:NEXT
50 COLLISION 1 : REM DISABLE
50 END
70 REM SPRITE <-> SPRITE INTERRUPT HANDLER
80 PRINT "BUMP RETURNS";BUMP(1)
90 RETURN: REM RETURN FROM INTERRUPT
```

SPRSAV

Token: \$FE \$16

Format: **SPRSAV** source, destination

Usage: Copies sprite data.

source = sprite number or string variable.

destination = sprite number or string variable.

Remarks: Both, source and destination can be either a sprite number or a string variable. But they must not be both a string variable. A simple string assignment can be used for such cases.

Example: Using **SPRSAV**:

```
10 BLOAD "SPRITEDATA",P1600 :REM LOAD DATA FOR SPRITE 1
20 SPRITE 1,1 :REM TURN SPRITE 1 ON
30 SPRSAV 1,2 :REM COPY SPRITE 1 DATA TO 2
40 SPRITE 2,1 :REM TURN SPRITE 2 ON
50 SPRSAV 1,A$ :REM SAVE SPRITE 1 DATA IN STRING
```

SQR

Token: \$BA

Format: **SQR**(numeric expression)

Usage: The **SQR** function returns the square root of the argument.

Remarks: The argument must not be negative.

Example: Using **SQR**

```
PRINT SQR(2)  
1.41421356
```

STEP

Token: \$A9

Format: **FOR index=start TO end [STEP step] ... NEXT [index]**

Usage: The **STEP** keyword is an optional part of a **FOR** loop.

The **index** variable may be incremented or decremented by a constant value on each iteration. The default is to increment the variable by 1. The index variable must be a real variable.

The **start** value is used to initialize the index.

The **end** value is used at the end of the loop and controls, whether the next iteration will be started or the loop exited.

The **step** value defines the change applied to the index variable at the end of the loop. Positive step values increment it, while negative values decrement it. It defaults to 1.0 if not specified.

Remarks: For positive increments **end** must be greater or equal than **start**, for negative increments **end** must be less or equal than **start**.

It is bad programming style to change the value of the index variable inside the loop or to jump into or out of the loop body with **GOTO**.

Example: Using **STEP**

```
10 FOR D=0 TO 360 STEP 30
20 R = D * π / 180
30 PRINT D;R;SIN(R);COS(R);TAN(R)
40 NEXT D
```

STOP

Token: \$90

Format: **STOP**

Usage: Stops the execution of the BASIC program. A message tells the line number of the break. The **READY.** prompt appears and the computer goes into direct mode waiting for keyboard input. The program execution can be resumed with the command **CONT**.

Remarks: All variable definitions are still valid after **STOP**. They may be inspected or altered and the program may be continued with the **CONT** statement. Every editing of the program source makes continuation impossible, however.

Example: Using **STOP**

```
10 IF V < 0 THEN STOP : REM NEGATIVE NUMBERS STOP THE PROGRAM
20 PRINT SQR(V)       : REM PRINT SQUARE ROOT
```

STR\$

Token: \$C4

Format: **STR\$(numeric expression)**

Usage: Returns a string containing the formatted value of the argument, as if it were printed to the string.

Example: Using **STR\$**:

```
A$ = "THE VALUE OF PI IS " + STR$(PI)
PRINT A$
THE VALUE OF PI IS 3.14159265
```

SYS

Token: \$9E

Format: **SYS** address [, areg, xreg, yreg, zreg, sreg]

Usage: Calls a machine language subroutine. This can be a ROM resident kernel or BASIC subroutine or a routine in RAM, which was loaded or poked to RAM before.

The CPU registers are loaded with the arguments, if specified. Then a subroutine call **JSR address** is performed. The called routine should exit with a **RTS** instruction. Then the register contents will be saved and the execution of the BASIC program continues.

address = start address of the subroutine.

areg = variable gets accumulator value.

xreg = variable gets X register value.

yreg = variable gets Y register value.

zreg = variable gets Z register value.

sreg = variable gets status register value.

The **SYS** command uses the current bank as set with the **BANK** command.

Remarks: The register values after a **SYS** call are stored in system memory. This enables the command **RREG** to retrieve these values.

Example: Using **SYS**:

```
10 BANK 128
20 BLOAD "ML PROG",8192
30 SYS 8192
40 RREG A,X,Y,Z,S
50 PRINT "REGISTER: ";A;X;Y;Z;S
```

TAB

Token: \$A3

Format: TAB(column)

Usage: Positions the cursor at **column**. This is only done, if the target column is right of the current cursor column, otherwise nothing happens. The column count starts with 0 for the left most column.

Remarks: This function must not be confused with the **TAB** key, which advances the cursor to the next tabstop.

Example: Using **TAB**

```
10 FOR I=1 TO 5
20 READ A$
30 PRINT "*" A$ TAB(10) "*"
40 NEXT I
50 END
60 DATA ONE,TWO,THREE,FOUR,FIVE

RUN
* ONE      *
* TWO      *
* THREE    *
* FOUR     *
* FIVE     *
```

TAN

Token: \$C0

Format: TAN(numeric expression)

Usage: Returns the tangent of the argument. The argument is expected in units of **[radians]**.

Remarks: An argument in units of **[degrees]** can be converted to **[radians]** by multiplication with $\pi/180$.

Example: Using TAN

```
PRINT TAN(0.7)
.84228838

X=45:PRINT TAN(X *  $\pi$  / 180)
.999999999
```

TEMPO

Token: \$FE \$05

Format: TEMPO speed

Usage: Sets the playback speed for the **PLAY** command.

speed = 1 -> 255.

The duration of a whole note is computed with $duration = 24/speed$.

Example: Using **TEMPO**

```
10 ENVELOPE 9,10,5,10,5,2,4000:PLAY "T9"  
20 VOL 8  
30 TEMPO 24      :REM PLAY EACH NOTE FOR ONE SECOND  
40 PLAY "C D E F G A B"  
50 PLAY "U5 V1 C D E F G A B"
```

THEN

Token: \$A7

Format: **IF expression THEN true clause ELSE false clause**

Usage: The **THEN** keyword is part of an **IF** statement.

expression is a logical or numeric expression. A numerical expression is evaluated as **FALSE** if the value is zero and **TRUE** for any non zero value.

true clause are one or more statements starting directly after **THEN** on the same line. A linenumber after **THEN** performs a **GOTO** to that line.

false clause are one or more statements starting directly after **ELSE** on the same line. A linenumber after **ELSE** performs a **GOTO** to that line.

Remarks: The standard **IF ... THEN ... ELSE** structure is restricted to a single line. But the **true clause** or **false clause** may be expanded to several lines using a compound statement bracketed with the keywords **BEGIN** and **BEND**.

Example: Using **THEN**

```
10 IF V < 0 THEN PRINT RED$;:ELSE PRINT BLACK$;  
20 PRINT V : REM PRINT NEGATIVE NUMBERS IN RED  
30 INPUT "END PROGRAM:(Y/N)";A$  
40 IF A$="Y" THEN END  
50 IF A$="N" THEN 10:ELSE 30
```

TO

Token: \$A4

Format: keyword **TO**

Usage: **TO** is a secondary keyword used in combination with primary keywords like **GO**, **FOR**, **BACKUP**, **BSAVE**, **CHANGE**, **CONCAT**, **COPY**, **RENAME** and **SET DISK**

Remarks: The keyword **TO** cannot be used on its own.

Example: Using **TO**

```
10 GO TO 1000 :REM AS GOTO 1000
20 GOTO 1000 :REM SHORTER AND FASTER
30 FOR I=1 TO 10 :REM TO IS PART OF THE LOOP
40 PRINT I:NEXT :REM LOOP END
50 COPY "CODES" TO "BACKUP" :REM COPY SINGLE FILE
```

TRAP

Token: \$D7

Format: **TRAP** [**line number**]

Usage: **TRAP** with a valid line number activates the BASIC error handler with following consequences: In case of an error the BASIC interpreter does not stop with an error message, but saves execution pointer and line number, places the error number into the system variable **ER** and jumps to the line number of the TRAP command. The trapping routine can examine **ER** and decide, whether to **STOP** or **RESUME** execution.

TRAP with no argument disables the error handler. Errors will be handled by the normal system routines.

Example: Using **TRAP**

```
10 TRAP 100
20 FOR I=1 TO 100
30 PRINT EXP(I)
40 NEXT
50 PRINT "STOPPED FOR I =";I
60 END
100 PRINT ERR$(ER): RESUME 50
```

TROFF

Token: \$D9

Format: TROFF

Usage: Turns off trace mode (switched on by **TRON**).

Example: Using **TROFF**

```
10 TRON           :REM ACTIVATE TRACE MODE
20 FOR I=85 TO 100
30 PRINT I;EXP(I)
40 NEXT
50 TROFF          :REM DEACTIVATE TRACE MODE

RUN
[10][20][30] 85  8.22301268E+36
[40][30] 86  2.2352466E+37
[40][30] 87  6.0760302E+37
[40][30] 88  1.65163625E+38
[40][30] 89
?OVERFLOW ERROR IN 30
READY.
```

TRON

Token: \$D8

Format: TRON

Usage: Turns on trace mode.

Example: Using **TRON**

```
10 TRON           :REM ACTIVATE TRACE MODE
20 FOR I=85 TO 100
30 PRINT I;EXP(I)
40 NEXT
50 TROFF          :REM DEACTIVATE TRACE MODE

RUN
[10][20][30] 85  8.22301268E+36
[40][30] 86  2.2352466E+37
[40][30] 87  6.0760302E+37
[40][30] 88  1.65163625E+38
[40][30] 89
?OVERFLOW ERROR IN 30
READY.
```

TYPE

Token: \$FE \$27

Format: **TYPE filename [,D drive] [,U unit]**

Usage: types the contents of a file containing text in PETSCII code.

filename is either a quoted string, e.g. **"data"** or a string expression in parentheses, e.g. **(FN\$)**

drive = drive # in dual drive disk units.

The drive # defaults to 0 and can be omitted on single drive units like the 1581, 1571 or 1541 series.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to **8**.

Remarks: This command cannot be used to type BASIC programs. Use **LIST** for programs. **TYPE** can only process SEQ or USR files containing records of PETSCII text, delimited by the **CR** = CHR\$(13) character.

Example: Using **TYPE**

```
TYPE "README"  
TYPE "README 1ST",U9
```

UNTIL

Token: \$FC

Format: **DO ... LOOP**
DO [<**UNTIL** | **WHILE**> <logical expr.>]
... statements [**EXIT**]
LOOP [<**UNTIL** | **WHILE**> <logical expr.>]

Usage: The **DO** and **LOOP** keywords define the start and end of the most versatile BASIC loop. Using **DO** and **LOOP** alone, without any modifiers creates an infinite loop, that can be left by the **EXIT** statement only. The loop can be controlled by adding an **UNTIL** or a **WHILE** statement after the **DO** or **LOOP**.

Remarks: **DO** loops may be nested. An **EXIT** statement exits the current loop only.

Example: Using **DO** and **LOOP**.

```
10 PW$="":DO
20 GET A$:PW$=PW$+A$
30 LOOP UNTIL LEN(PW$)>7 OR A$=CHR$(13)

10 DO : REM WAIT FOR USER DECISION
20 GET A$
30 LOOP UNTIL A$='Y' OR A$='N' OR A$='y' OR A$='n'

10 DO WHILE ABS(EPS) > 0.001
20 GOSUB 2000 : REM ITERATION SUBROUTINE
30 LOOP

10 I%=0 : REM INTEGER LOOP 1 -> 100
20 DO I%=I%+1
30 LOOP WHILE I% < 101
```

USING

Token: \$FB

Format: **PRINT** [**# channel**,] **USING**, **format**, **arguments**

Usage: **USING** is a secondary keyword used after **PRINT** or **PRINT#**.

It defines the format string for the argument list. The values are printed following the directives of the format string.

channel : must be opened for output by an **OPEN** or **DOPEN** statement. If no channel is specified, the output goes to the screen.

format : A string which defines the rules for formatting.

numeric argument : The '#' characters set the position and width of the output string.

'+' or '-' set the sign option.

'.' sets the position of the decimal point.

',' can be inserted into large numbers.

'\$' sets the position of the currency symbol.

^^^ reserves place for the exponent.

string argument : The string may consist of printable characters and control codes. Printable characters are printed to the cursor position, while control codes are executed. The number of '#' characters sets the width of the output, a '=' sign centers and a '>' character right justifies the output.

, : A comma acts like a tabulator. ; : A semicolon acts as a separator between arguments of the list. Other than the comma character it does not put in any additional characters. A semicolon at the end of the argument list suppresses the automatic return character.

Example: Using **PRINT USING**

```
10 X = 12.34: A$ = "MEGA 65"
30 PRINT USING "###.##"; X      : REM "12.34"
40 PRINT USING "###"; X        : REM " 12"
50 PRINT USING "#####"; A$    : REM "MEGA"
60 PRINT USING "#####"; A$    : REM "MEGA 65 "
70 PRINT USING "-#####"; A$   : REM " MEGA 65 "
80 PRINT USING "#####>#"; A$  : REM "  MEGA 65"
```

USR

Token: \$B7

Format: **USR(numeric expression)**

Usage: Using the function **USR(X)** in a numeric expression, puts the argument into the floating point accumulator 1 and jumps to the address \$02F7 expecting the address of the machine language user routine in \$02F8 - \$02F9. After executing the user routine, BASIC returns the contents of the floating point accumulator 1, which should be set by the user routine..

Remarks: Banks 0 -> 127 give access to RAM or ROM banks. Banks > 127 are used to access I/O and SYSTEM like VIC, SID, FDC, etc.

Example: Using **USR**

```
10 UX = DEC("7F00")           :REM ADDRESS OF USER ROUTINE
20 BANK 128                     :REM SELECT SYSTEM BANK
30 BLOAD "ML-PROG",P(UX)       :REM LOAD USER ROUTINE
40 POKE (DEC("2F8")),UX AND 255 :REM USR JUMP TARGET LOW
50 POKE (DEC("2F9")),UX / 256  :REM USR JUMP TARGET HIGH
60 PRINT USR(π)                :REM PRINT RESULT FOR ARGUMENT PI
```

VAL

Token: \$C5

Format: **VAL**(string expression)

Usage: Converts a string to a floating point value.
This function acts like reading from a string.

Remarks: A string containing not a valid number will not produce an error but return 0 as result.

Example: Using **VAL**

```
PRINT VAL("78E2")
7800

PRINT VAL("7+5")
7

PRINT VAL("1.256")
1.256

PRINT VAL("$FFFF")
0
```

VERIFY

Token: \$95

Format: **VERIFY** filename [,unit [,binflag]]

Usage: This command is obsolete in BASIC-10, where the commands **DVERIFY** and **BVERIFY** are better alternatives.

VERIFY with no **binflag** compares a BASIC program in memory with a disk file of type PRG. It does the same as **DVERIFY**, but with a different syntax.

VERIFY with **binflag** compares a binary file in memory with a disk file of type PRG. It does the same as **BVERIFY**, but with a different syntax.

filename is either a quoted string, e.g. "**prog**" or a string expression.

unit = device number on the IEC bus. Typically in the range 8 to 11 for disk units. If a variable is used, it must be put in parentheses. The unit # defaults to 8.

Remarks: **VERIFY** can only test for equality. It gives no information about the number or position of different valued bytes. The command exits either with the message **OK** or with **VERIFY ERROR**.

Example: Using **VERIFY**

```
VERIFY "ADVENTURE"  
VERIFY "ZORK-I",9  
VERIFY "1:DUNGEON",10
```

VOL

Token: \$DB

Format: VOL volume

Usage: Sets the volume for sound output with **SOUND** or **PLAY**.
volume = 0 (off) -> 15 (loudest).

Remarks: This volume setting affects all voices.

Example: Using VOL

```
10 ENVELOPE 9,10,5,10,5,2,4000:PLAY "T9"  
20 VOL 8  
30 TEMPO 100  
40 PLAY "C D E F G A B"  
50 PLAY "U5 V1 C D E F G A B"
```

WAIT

Token: \$92

Format: **WAIT** **address**, **andmask** [, **xormask**]

Usage: Pauses the BASIC program until a requested bit pattern is read from the given address.

address = the address at the current memory bank, which is read.

andmask = and mask applied.

xormask = xor mask applied.

WAIT reads the byte value from **address** and applies the masks:
result = PEEK(address) AND andmask XOR xormask

The pause ends if the result is nonzero, otherwise the reading is repeated. This may hang the computer infinitely, if the condition is never met.

Remarks: This command is typically used to examine hardware registers or system variables and wait for an event, e.g. joystick event, mouse event, keyboard press or a special raster line.

Example: Using **WAIT**

```
10 BANK 128
20 WAIT 211,1           :REM WAIT FOR SHIFT KEY BEING PRESSED
```

WHILE

Token: \$ED

Format: **DO ... LOOP**
DO [<**UNTIL** | **WHILE**> <logical expr.>]
... statements [**EXIT**]
LOOP [<**UNTIL** | **WHILE**> <logical expr.>]

Usage: The **DO** and **LOOP** keywords define the start and end of the most versatile BASIC loop. Using **DO** and **LOOP** alone, without any modifiers creates an infinite loop, that can be left by the **EXIT** statement only. The loop can be controlled by adding an **UNTIL** or a **WHILE** statement after the **DO** or **LOOP**.

Remarks: **DO** loops may be nested. An **EXIT** statement exits the current loop only.

Example: Using **DO** and **LOOP**

```
10 PW$="":DO
20 GET A$:PW$=PW$+A$
30 LOOP UNTIL LEN(PW$)>7 OR A$=CHR$(13)

10 DO : REM WAIT FOR USER DECISION
20 GET A$
30 LOOP UNTIL A$='Y' OR A$='N' OR A$='y' OR A$='n'

10 DO WHILE ABS(EPS) > 0.001
20 GOSUB 2000 : REM ITERATION SUBROUTINE
30 LOOP

10 I%=0 : REM INTEGER LOOP 1 -> 100
20 DO I%=I%+1
30 LOOP WHILE I% < 101
```

WINDOW

Token: \$FE \$1A

Format: **WINDOW** *left, top, right, bottom* [,clear]

Usage: Sets the text screen window.

left = left column

top = top row

right = right column

bottom = bottom row

clear = clear text window flag

The row values count from 0 to 24.

The column values count from 0 to 79 or 39 depending on the screen mode.

Remarks: There can be only one window on the screen. Striking the HOME key twice or printing CHR\$(19)CHR\$(19) will reset the window to the default full screen.

Example: Using **WINDOW**

```
10 WINDOW 0,1,79,24      :REM SCREEN WITHOUT TOP ROW
20 WINDOW 0,0,79,24,1    :REM FULL SCREEN WINDOW CLEARED
30 WINDOW 0,12,79,24     :REM LOWER HALF OF SCREEN
40 WINDOW 20,5,59,15     :REM SMALL CENTERED WINDOW
```

Special Keyboard Controls and Sequences

- **ASCII Codes and CHR\$**
- **Control codes**
- **Shifted codes**
- **Escape Sequences**

ASCII CODES AND CHR\$

You can use the PRINT CHR\$(X) statement to print a character. Below is the full table of ASCII codes you can print by index. For example, by using index 65 from the table below as: PRINT CHR\$(65) you will print the letter 'A'.

You can also do the reverse with the ASC statement. For example: PRINT ASC("A") Will output 65, which matches in the ASCII code table.

CHR\$	Prints	CHR\$	Prints	CHR\$	Prints

CONTROL CODES

Keyboard Control	Function
CTRL + 1 to 8	Choose from the first range of colours.
CTRL + T	Backspace the character immediately to the left and to shift all rightmost characters one position to the left. This is the same function as the Backspace key.
CTRL + Z	Tabs the cursor to the left.
CTRL + E	Restores the colour of the cursor back to the default white.
CTRL + Q	moves the cursor down one line at a time. This is the same function produced by the Cursor Down key.
CTRL + G	produces a bell tone.
CTRL + J	is a line feed and moves the cursor down one row. This is the same function produced by the  key.
CTRL + U	backs up to the start of the previous word, or unbroken string of characters. If there are no characters between the current cursor position and the start of the line, the cursor will move to the first column of the current line.
CTRL + W	advances forward to the start of the next word, or unbroken string of characters. If there are no characters between the current cursor position and the end of the line, the cursor will move to the first column of the next line.

Keyboard Control	Function
CTRL + B	turns on underline text mode. Turn off underline mode by pressing ESC then O .
CTRL + N	changes the text case mode from uppercase to lowercase.
CTRL + M	is the carriage return. This is the same function as the RETURN key.
CTRL + J	is the same function as → .
CTRL + I	tabs forward to the right.
CTRL + X	sets or clears the current screen column as a tab position. CTRL + I or Z will jump to all positions set with X . When there are no more tab positions, the cursor will stay at the end of the line with CTRL and I , or move to the start of the line in the case of CTRL and Z .
CTRL + K	locks the uppercase/lowercase mode switch usually performed with M and SHIFT keys.
CTRL + L	enables the uppercase/lowercase mode switch that is performed with the M and SHIFT keys.
CTRL + [is the same as pressing the ESC key.
CTRL + *	enters the Matrix Mode Debugger.

SHIFTED CODES

Keyboard Control	Function
 + 	Insert a character in the current cursor position and move all characters to the right by one position.
 + 	Clear home, clear the entire screen and move the cursor to the home position.

ESCAPE SEQUENCES

To perform an Escape Sequence, press and release the **ESC** key. Then press one of the following keys to perform the sequence:

Key	Sequence
X	Clears the screen and toggles between 40 and 80 column modes.
@	Clears the screen starting from the cursor to the end of the screen.
A	Enables the auto-insert mode. Any keys pressed will insert before other characters.
B	Sets the bottom-right window area of the screen at the cursor position. All typed characters and screen activity will be restricted to the area. Also see ESC then T .
C	Disables auto-insert mode, going back to overwrite mode.
D	Deletes the current line and moves other lines up one position.
E	Sets the cursor to non-flashing mode.
F	Sets the cursor to regular flashing mode.
G	Enables the bell which can be sounded using CTRL and G .
H	Disable the bell so that pressing CTRL and G will have no effect.
I	Inserts an empty line in the current cursor position and moves all subsequent lines down one position.

Key	Sequence
J	Moves the cursor to start of current line.
K	Move to end of the last non-whitespace character on the current line.
L	Enables scrolling when the cursor down key is pressed at the bottom of the screen.
M	Disables scrolling. When pressing the cursor down key at the bottom on the screen, the cursor will move to the top of the screen. The cursor is restricted at the top of the screen with the Cursor up key.
O	Cancels the quote, reverse, underline and flash modes.
P	Erases all characters from the cursor to the start of current line.
Q	Erases all characters from the cursor to the end of current line.
S	Switches the VIC-IV to colour range 16-31. These colours can be accessed with CTRL and keys 1 to 8 or M and keys 1 to 8 .
T	Set top-left window area of the screen at the cursor position. All typed characters and screen activity will be restricted to the area. Also see ESC then B .
U	Switches the VIC-IV to colour range 0-15. These colours can be accessed with CTRL and keys 1 to 8 or M and keys 1 to 8 .

Key	Sequence
V	Scrolls the entire screen up one line.
W	Scrolls the entire screen down one line.
X	Toggles the 40/80 column display. The screen will also clear home.
Y	Set the default tab stops (every 8 spaces) for the entire screen.
Z	Clears all the tab stops. Any tabbing with CTRL and I will move the cursor to the end of the line.
1 to 8	Choose from the second range of colours.

- **Notations and Bases**
- **Operations**
- **Signed and Unsigned Numbers**
- **Bitwise Logical Operators**
- **Converting Numbers**

NUMBERS

Simple computer programs, such as most of the introductory BASIC programs in this book, do not require an understanding of mathematics or much knowledge about the inner workings of the computer. This is because BASIC is considered a high-level programming language. It lets us program the computer somewhat indirectly, yet still gives us control over the computer's features. Most of the time, we don't need to concern ourselves with the computer's internal architecture, which is why BASIC is user friendly and accessible.

As you acquire deeper knowledge and become more experienced, you will often want to instruct the computer to perform complex or specialized tasks that differ from the examples given in this book. Perhaps for reasons of efficiency, you may also want to exercise direct and precise control over the contents of the computer's memory. This is especially true for applications that deal with advanced graphics and sound. Such operations are closer to the hardware and are therefore considered low-level. Some simple mathematical knowledge is required to be able to use these low-level features effectively.

The collective position of the tiny switches inside the computer—whether each switch is on or off—is the state of the computer. It is natural to associate numerical concepts with this state. Numbers let us understand and manipulate the internals of the machine via logic and arithmetic operations. Numbers also let us encode the two essential and important pieces of information that lie within every computer program: *instructions* and *data*.

A program's instructions tell a computer what to do and how to do it. For example, the action of outputting a text string to the screen via the statement **PRINT** is an instruction. The action of displaying a sprite and the action of changing the screen's border color are instructions too. Behind the scenes, every instruction you give to the computer is associated with one or more numbers (which, in turn, correspond to the tiny switches inside the computer being switched on or off). Most of the time these instructions won't look like numbers to you. Instead, they might take the form of statements in BASIC.

A program's data consists of information. For example, the greeting "HELLO MEGA65!" is PETSCII character data in the form of a text string. The graphical design of a sprite might be pixel data in the form of a hero for a game. And the color data of the screen's border might represent orange. Again, behind the scenes, every piece of data you give to the computer is associated with one or more numbers. Data is sometimes given directly next to the statement to which it applies. This data is referred to as a parameter or argument (such as when changing the screen colour with a **BACKGROUND 1** statement). Data

may also be given within the program via the BASIC statement **DATA** which accepts a list of comma-separated values.

All such numbers—regardless of whether they represent instructions or data—reside in the computer’s memory. Although the computer’s memory is highly structured, the computer does not distinguish between instructions and data, nor does it have separate areas of memory for each kind of information. Instead, both are stored in whichever memory location is considered convenient. Whether a given memory location’s contents is part of the program’s instructions or is part of the program’s data largely depends on your viewpoint, the program being written and the needs of the programmer.

Although BASIC is a high-level language, it still provides statements that allow programmers to manipulate the computer’s memory efficiently. The statement **PEEK** lets us read the information from a specified memory location: we can inspect the contents of a memory address. The statement **POKE** lets us store information inside a specified memory location: we can modify the contents of a memory address so that it is set to a given value.

NOTATIONS AND BASES

We now take a look at numbers.

Numbers are ideas about quantity and magnitude. In order to manipulate numbers and determine relationships between them, it’s important for them to have a unique form. This brings us to the idea of the symbolic representation of numbers using a positional notation. In this appendix we’ll restrict our discussion to whole numbers, which are also called *integers*.

The *decimal* representation of numbers is the one with which you will be most comfortable since it is the one you were taught at school. Decimal notation uses the ten Hindu-Arabic numerals 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9 and is thus referred to as a base 10 numeral system. As we shall see later, in order to express large numbers in decimal, we use a positional system in which we juxtapose digits into columns to form a bigger number.

For example, 53280 is a decimal number. Each such digit (0 to 9) in a decimal number represents a multiple of some power of 10. When a BASIC statement (such as **PEEK** or **POKE**) requires an integer as a parameter, that parameter is given in the decimal form.

Although the decimal notation feels natural and comfortable for humans to use, modern computers, at their most fundamental level, use a different notation. This notation is called *binary*. It is also referred to as a base 2 numeral

system because it uses only two Hindu-Arabic numerals: 0 and 1. Binary reflects the fact that each of the tiny switches inside the computer must be in exactly one of two mutually exclusive states: on or off. The number 0 is associated with off and the number 1 is associated with on. Binary is the simplest notation that captures this idea. In order to express large numbers in binary, we use a positional system in which we juxtapose digits into columns to form a bigger number and prefix it with a % sign.

For example, %1001 0110 is a binary number. Each such digit (0 or 1) in a binary number represents a multiple of some power of 2.

We'll see later how we can use special BASIC statements to manipulate the patterns of ones and zeros present in a binary number to change the state of the switches associated with it. Effectively, we can toggle individual switches on or off, as needed.

A third notation called *hexadecimal* is also often used. This is a base 16 numeral system. Because it uses more than ten digits, we need to use some letters to represent the extra digits. Hexadecimal uses the ten Hindu-Arabic digits 0 to 9 as well as the six Latin alphabetic characters as "digits" (A, B, C, D, E and F) to represent the numbers 10 to 15. This gives a total of sixteen symbols for the numbers 0 to 15. To express a large number in hexadecimal, we use a positional system in which we juxtapose digits into columns to form a bigger number and prefix it with a \$ sign.

For example, \$E7 is a hexadecimal number. Each such digit (0 to 9 and A to F) in a hexadecimal number represents a multiple of some power of 16.

Hexadecimal is not often used when programming in BASIC. It is more commonly used when programming in low-level languages like machine code or assembly language. It also appears in computer memory maps and its brevity makes it a useful notation, so it is described here.

Always remember that decimal, binary and hexadecimal are just different notations for numbers. A notation just changes the way the number is written (i.e., the way it looks on paper or on the screen), but its intrinsic value remains unchanged. A notation is essentially different ways of representing the same thing. The reason that we use different notations is that each notation lends itself more naturally to a different task.

When using decimal, binary and hexadecimal for extended periods you may find it handy to have a scientific pocket calculator with a programmer mode. Such calculators can convert between bases with the press of a button. They can also add, subtract, multiply and divide, and perform various bitwise logical operations.

The BASIC listing for this appendix is a utility program that converts individual numbers into different bases. It can also convert multiple numbers within a specified range.

Although these concepts might be new now, with some practice they'll soon seem like second nature. We'll look at ways of expressing numbers in more detail. Later, we'll also investigate the various operations that we can perform on such numbers.

Decimal

When representing integers using decimal notation, each column in the number is for a different power of 10. The rightmost position represents the number of units (because $10^0 = 1$) and each column to the left of it is 10 times larger than the column before it. The rightmost column is called the units column. Columns to the left of it are labelled tens (because $10^1 = 10$), hundreds (because $10^2 = 100$), thousands (because $10^3 = 1000$), and so on.

To give an example, the integer 53280 represents the total of 5 lots of 10000, 3 lots of 1000, 2 lots of 100, 8 lots of 10 and 0 units. This can be seen more clearly if we break the integer up into distinct parts, by column.

Since

$$53280 = 50000 + 3000 + 200 + 80 + 0$$

we can present this as a table with the sum of each column at the bottom.

TEN THOUSANDS	THOUSANDS	HUNDREDS	TENS	UNITS
$10^4 = 10000$	$10^3 = 1000$	$10^2 = 100$	$10^1 = 10$	$10^0 = 1$
5	0	0	0	0
	3	0	0	0
		2	0	0
			8	0
				0
5	3	2	8	0

Another way of stating this is to write the expression using multiples of powers of 10.

$$53280 = (5 \times 10^4) + (3 \times 10^3) + (2 \times 10^2) + (8 \times 10^1) + (0 \times 10^0)$$

Alternatively

$$53280 = (5 \times 10000) + (3 \times 1000) + (2 \times 100) + (8 \times 10) + (0 \times 1)$$

We now introduce some useful terminology that is associated with decimal numbers.

The rightmost digit of a decimal number is called the least significant digit, because, being the smallest multiplier of a power of 10, it contributes the least to the number's magnitude. Each digit to the left of this digit has increasing significance. The leftmost (non-zero) digit of the decimal number is called the most significant digit, because, being the largest multiplier of a power of 10, it contributes the most to the number's magnitude.

For example, in the decimal number 53280, the digit 0 is the least significant digit and the digit 5 is the most significant digit.

A decimal number a is m orders of magnitude greater than the decimal number b if $a = b \times (10^m)$. For example, 50000 is three orders of magnitude greater than 50, because it has three more zeros. This terminology can be useful when making comparisons between numbers or when comparing the time efficiency or space efficiency of two programs with respect to the sizes of the given inputs.

Note that unlike binary (which uses a conventional % prefix) and hexadecimal (which uses a conventional \$ prefix), decimal numbers are given no special prefix. In some textbooks you might see such numbers with a subscript instead. So decimal numbers will have a subscripted 10, binary numbers will have a subscripted 2, and hexadecimal numbers will have a subscripted 16.

Another useful concept is the idea of signed and unsigned decimal integers.

A signed decimal integer can be positive or negative or zero. To represent a signed decimal integer, we prefix it with either a + sign or a - sign. (By convention, zero, which is neither positive nor negative, is given the + sign.)

If, on the other hand, a decimal integer is unsigned it must be either zero or positive and does not have a negative representation. This can be illustrated with the BASIC statements **PEEK** and **POKE**. When we use **PEEK** to return the value contained within a memory location, we get back an unsigned decimal number. For example, the statement **PRINT (PEEK (49152))** outputs the contents of memory location 49152 to the screen as an unsigned decimal number. Note that the memory address that we gave to **PEEK** is itself an unsigned integer. When we use **POKE** to store a value inside a memory location, both the memory address and the value to store inside it are given as unsigned integers. For example, the statement **POKE 49152, 128** stores the unsigned decimal integer 128 into the memory address given by the unsigned decimal integer 49152.

Each memory location in the MEGA65 can store a decimal integer between 0 and 255. This corresponds to the smallest and largest decimal integers that can be represented using eight binary digits (eight bits). Also, the memory addresses are decimal integers between 0 and 65535. This corresponds to the smallest and largest decimal integers that can be represented using sixteen binary digits (sixteen bits).

Note that the largest number expressible using d decimal digits is $10^d - 1$. (This number will have d nines in its representation.)

Binary

Binary notation uses powers of 2 (instead of 10 which is for decimal). The rightmost position represents the number of units (because $2^0 = 1$) and each column to the left of it is 2 times larger than the column before it. Columns to the left of the rightmost column are the twos column (because $2^1 = 2$), the fours column (because $2^2 = 4$), the eights column (because $2^3 = 8$), and so on.

As an example, the integer %1101 0011 uses exactly eight binary digits and represents the total of 1 lot of 128, 1 lot of 64, 0 lots of 32, 1 lot of 16, 0 lots of 8, 0 lots of 4, 1 lot of 2 and 1 unit.

We can break this integer up into distinct parts, by column.

Since

$$\%1101\ 0011 = \%1000\ 0000 + \%100\ 0000 + \%00\ 0000 + \%1\ 0000 + \%0000 + \%000 + \%10 + \%1$$

we can present this as a table with the sum of each column at the bottom.

ONE HUNDRED AND TWENTY-EIGHTS	SIXTY- FOURS	THIRTY- TWO	SIXTEENS	EIGHTS	FOURS	TWOS	UNITS
$2^7 = 128$	$2^6 = 64$	$2^5 = 32$	$2^4 = 16$	$2^3 = 8$	$2^2 = 4$	$2^1 = 2$	$2^0 = 1$
1	0	0	0	0	0	0	0
	1	0	0	0	0	0	0
		0	0	0	0	0	0
			1	0	0	0	0
				0	0	0	0
					0	0	0
						1	0
							1
1	1	0	1	0	0	1	1

Another way of stating this is to write the expression in decimal, using multiples of powers of 2.

$$\%11010011 = (1 \times 2^7) + (1 \times 2^6) + (0 \times 2^5) + (1 \times 2^4) + (0 \times 2^3) + (0 \times 2^2) + (1 \times 2^1) + (1 \times 2^0)$$

Alternatively

$$\%11010011 = (1 \times 128) + (1 \times 64) + (0 \times 32) + (1 \times 16) + (0 \times 8) + (0 \times 4) + (1 \times 2) + (1 \times 1)$$

which is the same as writing

$$\%11010011 = 128 + 64 + 16 + 2 + 1$$

Binary has terminology of its own. Each binary digit in a binary number is called a *bit*. In an 8-bit number the bits are numbered consecutively with the least significant (i.e., rightmost) bit as bit 0 and the most significant (i.e., leftmost) bit as bit 7. In a 16-bit number the most significant bit is bit 15. A bit is said to be *set* if it equals 1. A bit is said to be *clear* if it equals 0. When a particular bit has a special meaning attached to it, we sometimes refer to it as a *flag*.

1	1	0	1	0	0	1	1
Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

As mentioned earlier, each memory location can store an integer between 0 and 255. The minimum corresponds to %0000 0000 and the maximum corresponds to %1111 1111, which are the smallest and largest numbers that can be represented using exactly eight bits. The memory addresses use 16 bits. The smallest memory address, represented in exactly sixteen bits, is %0000 0000 0000 0000 and this corresponds to the smallest 16-bit number. Likewise, the largest memory address, represented in exactly sixteen bits,

is %1111 1111 1111 1111 and this corresponds to the largest 16-bit number.

It is often convenient to refer to groups of bits by different names. For example, eight bits make a *byte* and 1024 bytes make a *kilobyte*. Half a byte is called a *nybble*.

Note that the largest number expressible using d binary digits is (in decimal) $2^d - 1$. (This number will have d ones in its representation.)

Hexadecimal

Hexadecimal notation uses powers of 16. Each of the sixteen hexadecimal numerals has an associated value in decimal.

Hexadecimal Numeral	Decimal Equivalent
\$0	0
\$1	1
\$2	2
\$3	3
\$4	4
\$5	5
\$6	6
\$7	7
\$8	8
\$9	9
\$A	10
\$B	11
\$C	12
\$D	13
\$E	14
\$F	15

The rightmost position in a hexadecimal number represents the number of ones (since $16^0 = 1$). Each column to the left of this digit is 16 times larger than the column before it. Columns to the left of the rightmost column are the 16-column (since $16^1 = 16$), the 256-column (since $16^2 = 256$), the 4096-column (since $16^3 = 4096$), and so on.

As an example, the integer \$A3F2 uses exactly four hexadecimal digits and represents the total of 10 lots of 4096 (because \$A = 10), 3 lots of 256

(because \$3 = 3), 15 lots of 16 (because \$F = 15) and 2 units (because \$2 = 2). We can break this integer up into distinct parts, by column.

Since

$$\text{\$A3F2} = \text{\$A000} + \text{\$300} + \text{\$F0} + \text{\$2}$$

we can present this as a table with the sum of each column at the bottom.

FOUR THOUSAND AND NINETY-SIXES	TWO HUNDRED AND FIFTY-SIXES	SIXTEENS	UNITS
$16^3 = 4096$	$16^2 = 256$	$16^1 = 16$	$16^0 = 1$
A	0	0	0
	3	0	0
		F	0
			2
A	3	F	2

Another way of stating this is to write the expression in decimal, using multiples of powers of 16.

$$\text{\$A3F2} = (10 \times 16^3) + (3 \times 16^2) + (15 \times 16^1) + (2 \times 16^0)$$

Alternatively

$$\text{\$A3F2} = (10 \times 4096) + (3 \times 256) + (15 \times 16) + (2 \times 1)$$

which is the same as writing

$$\text{\$A3F2} = 40960 + 768 + 240 + 2$$

Again, like binary and decimal, the rightmost digit is the least significant and the leftmost digit is the most significant.

Each memory location can store an integer between 0 and 255, and this corresponds to the hexadecimal numbers \$00 and \$FF. The hexadecimal number \$FFFF corresponds to 65535—the largest 16-bit number.

Hexadecimal notation is often more convenient to use and manipulate than binary. Binary numbers consist of a longer sequence of ones and zeros, while hexadecimal is much shorter and more compact. This is because one hexadecimal digit is equal to exactly four bits. So a two-digit hexadecimal number comprises of eight bits with the low nybble equaling the right digit and the high nybble equaling the left digit.

Note that the largest number expressible using d hexadecimal digits is (in decimal) $16^d - 1$. (This number will have d \$F symbols in its representation.)

OPERATIONS

In this section we'll take a tour of some familiar operations like counting and arithmetic, and we'll see how they apply to numbers written in binary and hexadecimal.

Then we'll take a look at various logical operations using logic gates. These operations are easy to understand. They're also very important when it comes to writing programs that have extensive numeric, graphic or sound capabilities.

Counting

If we consider carefully the process of *counting* in decimal, this will help us to understand how counting works when using binary and hexadecimal.

Let's suppose that we're counting in decimal and that we're starting at 0. Recall that the list of numerals for decimal is (in order) 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9. Notice that when we add 1 to 0 we obtain 1, and when we add 1 to 1 we obtain 2. We can continue in this manner, always adding 1:

$$\begin{aligned}0 + 1 &= 1 \\1 + 1 &= 2 \\2 + 1 &= 3 \\3 + 1 &= 4 \\4 + 1 &= 5 \\5 + 1 &= 6 \\6 + 1 &= 7 \\7 + 1 &= 8 \\8 + 1 &= 9\end{aligned}$$

Since 9 is the highest numeral in our list of numerals for decimal, we need some way of handling the following special addition: $9 + 1$. The answer is that we can reuse our old numerals all over again. In this important step, we reset the units column back to 0 and (at the same time) add 1 to the tens column. Since the tens column contained a 0, this gives us $9 + 1 = 10$. We say we "carried" the 1 over to the tens column while the units column cycled back to 0.

Using this technique, we can count as high as we like. The principle of counting for binary and hexadecimal is very much the same, except instead of using ten symbols, we get to use two symbols and sixteen symbols, respectively.

Let's take a look at counting in binary. Recall that the list of numerals for binary is (in order) just 0 and 1. So, if we begin counting at %0 and then add %1, we obtain %1 as the result:

$$\%0 + \%1 = \%1$$

Now, the sum %1 + %1 will cause us to perform the analogous step: we reset the units column back to zero and (at the same time) add %1 to the twos column. Since the twos column contained a %0, this gives us %1 + %1 = %10. We say we "carried" the %1 over to the twos column while the units column cycled back to %0. If we continue in this manner we can count higher.

$$\begin{aligned}\%1 + \%1 &= \%10 \\ \%10 + \%1 &= \%11 \\ \%11 + \%1 &= \%100 \\ \%100 + \%1 &= \%101 \\ \%101 + \%1 &= \%110 \\ \%110 + \%1 &= \%111 \\ \%111 + \%1 &= \%1000\end{aligned}$$

Now we'll look at counting in hexadecimal. The list of numerals for hexadecimal is (in order) 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E and F. If we begin counting at \$0 and repeatedly add \$1 we obtain:

$$\begin{aligned}\$0 + \$1 &= \$1 \\ \$1 + \$1 &= \$2 \\ \$2 + \$1 &= \$3 \\ \$3 + \$1 &= \$4 \\ \$4 + \$1 &= \$5 \\ \$5 + \$1 &= \$6 \\ \$6 + \$1 &= \$7 \\ \$7 + \$1 &= \$8 \\ \$8 + \$1 &= \$9 \\ \$9 + \$1 &= \$A \\ \$A + \$1 &= \$B \\ \$B + \$1 &= \$C \\ \$C + \$1 &= \$D \\ \$D + \$1 &= \$E \\ \$E + \$1 &= \$F\end{aligned}$$

Now, when we compute \$F + \$1 we must reset the units column back to \$0 and add \$1 to the sixteens column as that number is "carried".

$$\$F + \$1 = \$10$$

Again, this process allows us to count as high as we like.

Arithmetic

The standard arithmetic operations of addition, subtraction, multiplication and division are all possible using binary and hexadecimal.

Addition is done in the same way that addition is done using decimal, except that we use base 2 or base 16 as appropriate. Consider the following example for the addition of two binary numbers.

$$\begin{array}{r} \%110 \\ + \%111 \\ \hline \%1101 \end{array}$$

We obtain the result by first adding the units columns of both numbers. This gives us $\%0 + \%1 = \%1$ with nothing to carry into the next column. Then we add the twos columns of both numbers: $\%1 + \%1 = \%0$ with a $\%1$ to carry into the next column. We then add the fours columns (plus the carry) giving $(\%1 + \%1) + \%1 = \%1$ with a $\%1$ to carry into the next column. Last of all are the eights columns. Because these are effectively both zero we only concern ourselves with the carry which is $\%1$. So $(\%0 + \%0) + \%1 = \%1$. Thus, $\%1101$ is the sum.

Next is an example for the addition of two hexadecimal numbers.

$$\begin{array}{r} \$7D \\ + \$69 \\ \hline \$E6 \end{array}$$

We begin by adding the units columns of both numbers. This gives us $\$D + \$9 = \$6$ with a $\$1$ to carry into the next column. We then add the sixteens columns (plus the carry) giving $(\$7 + \$6) + \$1 = \E with nothing to carry and so $\$E6$ is the sum.

We now look at subtraction. As you might suspect, binary and hexadecimal subtraction follows a similar process to that of subtraction for decimal integers.

Consider the following subtraction of two binary numbers.

$$\begin{array}{r} \%1011 \\ - \%110 \\ \hline \%101 \end{array}$$

Starting in the units columns we perform the subtraction $\%1 - \%0 = \%1$. Next, in the twos columns we perform another subtraction $\%1 - \%1 = \%0$. Last of all we subtract the fours columns. This time, because $\%0$ is less than $\%1$, we'll

need to borrow a %1 from the eights column of the top number to make the subtraction. Thus we compute $\%10 - \%1 = \%1$ and deduct %1 from the eights column. The eights columns are now both zeros. Since $\%0 - \%0 = \%0$ and because this is the leading digit of the result we can drop it from the final answer. This gives %101 as the result.

Let's now look at the subtraction of two hexadecimal numbers.

$$\begin{array}{r} \$3D \\ - \$1F \\ \hline \$1E \end{array}$$

To perform this subtraction we compute the difference of the units columns. In order to do this, we note that because \$D is less than \$F we will need to borrow \$1 from the sixteens column of the top number to make the subtraction. Thus, we compute $\$1D - \$F = \$E$ and also compute $\$3 - \$1 = \$2$ in the sixteens column for the for the \$1 that we just borrowed. Next, we compute the difference of the sixteens column as $\$2 - \$1 = \$1$. This gives us a final answer of \$1E.

We won't give in depth examples of multiplication and division for binary and hexadecimal notation. Suffice to say that principles parallel those for the decimal system. Multiplication is repeated addition and division is repeated subtraction.

We will, however, point out a special type of multiplication and division for both binary and hexadecimal. This is particularly useful for manipulating binary and hexadecimal numbers.

For binary, multiplication by two is simple—just shift all bits to the left by one position and fill in the least significant bit with a %0. Division by two is simple too—just shift all bits to the right by one position and fill in the most significant bit with a %0. By doing these repeatedly we can multiply and divide by powers of two with ease.

Thus the binary number %111, when multiplied by eight has three extra zeros on the end of it and is equal to %111000. (Recall that $2^3 = 8$.) And the binary number %10100, when divided by four has two less digits and equals %101. (Recall that $2^2 = 4$.)

These are called left and right *bit shifts*. So if we say that we shift a number to the left four bit positions, we really mean that we multiplied it by $2^4 = 16$.

For hexadecimal, the situation is similar. Multiplication by sixteen is simple—just shift all digits to the left by one position and fill in the rightmost digit with a \$0. Division by sixteen is simple too—just shift all digits to the right by one

position. By doing this repeatedly we can multiply and divide by powers of sixteen with ease.

Thus the hexadecimal number \$F, when multiplied 256 has two extra zeros on the end of it and is equal to \$F00. (Recall that $16^2 = 256$.) And the hexadecimal number \$EA0, when divided by sixteen has one less digit and equals \$EA. (Recall that $16^1 = 16$.)

Logic Gates

There exist several so-called *logic gates*. The fundamental ones are NOT, AND, OR and XOR.

They let us set, clear and invert specific binary digits. For example, when dealing with sprites, we might want to clear bit 6 (i.e., make it equal to 0) and set bit 1 (i.e., make it equal to 1) at the same time for a particular graphics chip register. Certain logic gates will, when used in combination, let us do this.

Learning how these logic gates work is very important because they are the key to understanding how and why the computer executes programs as it does.

All logic gates accept one or more inputs and produce a single output. These inputs and outputs are always single binary digits (i.e., they are 1-bit numbers).

The NOT gate is the only gate that accepts exactly one bit as input. All other gates—AND, OR, and XOR—accept exactly two bits as input. All gates produce exactly one output, and that output is a single bit.

First, let's take a look at the simplest gate, the NOT gate.

The NOT gate behaves by inverting the input bit and returning this resulting bit as its output. This is summarized in the following table.

INPUT x	OUTPUT
0	1
1	0

We write NOT x where x is the input bit.

Next, we take a look at the AND gate.

As mentioned earlier, the AND gate accepts two bits as input and produces a single bit as output. The AND gate behaves in the following manner. Whenever both input bits are equal to 1 the result of the output bit is 1. For all other inputs the result of the output bit is 0. This is summarized in the following table.

INPUT X	INPUT Y	OUTPUT
0	0	0
0	1	0
1	0	0
1	1	1

We write x AND y where x and y are the input bits.

Next, we take a look at the OR gate.

The OR gate accepts two bits as input and produces a single bit as output. The OR gate behaves in the following manner. Whenever both input bits are equal to 0 the result is 0. For all other inputs the result of the output bit is 1. This is summarized in the following table.

INPUT X	INPUT Y	OUTPUT
0	0	0
0	1	1
1	0	1
1	1	1

We write x OR y where x and y are the input bits.

Last of all we look at the XOR gate.

The XOR gate accepts two bits as input and produces a single bit as output. The XOR gate behaves in the following manner. Whenever both input bits are equal in value the output bit is 0. Otherwise, both input bits are unequal in value and the output bit is 1. This is summarized in the following table.

INPUT X	INPUT Y	OUTPUT
0	0	0
0	1	1
1	0	1
1	1	0

We write x XOR y where x and y are the input bits.

Note that there do exist some other gates. They are easy to construct.

- NAND gate: this is an AND gate followed by a NOT gate
- NOR gate: this is an OR gate followed by a NOT gate
- XNOR gate: this is an XOR gate followed by a NOT gate

SIGNED AND UNSIGNED NUMBERS

So far we've largely focussed on unsigned integers. Unsigned integers have no positive or negative sign. They are always assumed to be positive. (For this purpose, zero is regarded as positive.)

Signed numbers, as mentioned earlier, can have a positive sign or a negative sign.

Signed numbers are represented by treating the most significant bit as a sign bit. This bit cannot be used for anything else. If the most significant bit is 0 then the result is interpreted as having a positive sign. Otherwise, the most significant bit is 1, and the result is interpreted as having a negative sign.

A signed 8-bit number can represent positive-sign numbers between 0 and 127, and negative-sign numbers between -1 and -128.

A signed 16-bit number can represent positive-sign numbers between 0 and 32767, and negative-sign numbers between -1 and -32768.

Reserving the most significant bit as the sign of the signed number effectively halves the range of the available positive numbers (i.e., compared to unsigned numbers), with the tradeoff being that we gain an equal quantity of negative numbers instead.

To negate any signed number, every bit in the signed number must be inverted and then 1 must be added to the result. Thus, negating 0000 0101 (which is the signed number +5) gives 1111 1011 (which is the signed number -5). As expected, performing the negation of this negative number gives us +5 again.

BITWISE LOGICAL OPERATORS

The BASIC statements **NOT**, **AND**, **OR** and **XOR** have functionality similar to that of the logic gates that they are named after.

The **NOT** statement must be given a 16-bit signed decimal integer as a parameter. It returns a 16-bit signed decimal integer as a result.

In the following example, all sixteen bits of the signed decimal number +0 are equal to 0. The **NOT** statement inverts all sixteen bits as per the NOT gate. This sets all sixteen bits. If we interpret the result as a signed decimal number, we obtain the answer of -1.

```
PRINT (NOT 0)
-1
```

As expected, repeating the **NOT** statement on the parameter of -1 gets us back to where we started, since all sixteen set bits become cleared.

```
PRINT (NOT -1)
0
```

The **AND** statement must be given two 16-bit signed decimal integers as parameters. The second parameter is called the *bit mask*. The statement returns a 16-bit signed decimal integer as a result, having changed each bit as per the AND gate.

In the following example, the number +253 is used as the first parameter. As a 16-bit signed decimal integer, this is equivalent to the following number in binary: %0000 0000 1111 1101. The **AND** statement uses a bit mask as the second parameter with a 16-bit signed decimal value of +239. In binary this is the number %0000 0000 1110 1110. If we use the AND logic gate table on corresponding pairs of bits, we obtain the 16-bit signed decimal integer +237 (which is %0000 0000 1110 1100 in binary).

```
PRINT (253 AND 239)
237
```

We can see this process more clearly in the following table.

	%0000 0000 1111 1101
AND	%0000 0000 1110 1110
	<hr/>
	%0000 0000 1110 1100
	<hr/>

Notice that each bit in the top row passes through unchanged wherever there is a 1 in the mask bit below it. Otherwise the bit in that position gets cleared.

The **OR** statement must be given two 16-bit signed decimal integers as parameters. The second parameter is called the *bit mask*. The statement returns a 16-bit signed decimal integer as a result, having changed each bit as per the OR gate.

In the following example, the number +240 is used as the first parameter. As a 16-bit signed decimal integer, this is equivalent to the following number in binary: %0000 0000 1111 0000. The **OR** statement uses a bit mask as the

second parameter with a 16-bit signed decimal value of +19. In binary this is the number %0000 0000 0001 0011. If we use the OR logic gate table on corresponding pairs of bits, we obtain the 16-bit signed decimal integer +243 (which is %0000 0000 1111 0011 in binary).

```
PRINT (240 OR 19)
243
```

We can see this process more clearly in the following table.

	%0000 0000 1111 0000
OR	%0000 0000 0001 0011
	<u>%0000 0000 1111 0011</u>

Notice that each bit in the top row passes through unchanged wherever there is a 0 in the mask bit below it. Otherwise the bit in that position gets set.

Next we look at the **XOR** statement. This statement must be given two 16-bit unsigned decimal integers as parameters. The second parameter is called the *bit mask*. The statement returns a 16-bit unsigned decimal integer as a result, having changed each bit as per the XOR gate.

In the following example, the number 14091 is used as the first parameter. As a 16-bit unsigned decimal integer, this is equivalent to the following number in binary: %0011 0111 0000 1011. The **XOR** statement uses a bit mask as the second parameter with a 16-bit unsigned decimal value of 8653. In binary this is the number %0010 0001 1100 1101. If we use the XOR logic gate table on corresponding pairs of bits, we obtain the 16-bit unsigned decimal integer 5830 (which is %0001 0110 1100 0110 in binary).

```
PRINT (XOR(14091,8653))
5830
```

We can see this process more clearly in the following table.

	%0011 0111 0000 1011
XOR	%0010 0001 1100 1101
	<u>%0001 0110 1100 0110</u>

Notice that when the bits are equal the resulting bit is 0. Otherwise the resulting bit is 1.

Much of the utility of these bitwise logical operators comes through combining them together into a compound statement. For example, the VIC II register to

enable sprites is memory address 53269. There are eight sprites (numbered 0 to 7) with each bit corresponding to a sprite's status. Now suppose we want to turn off sprite 5 and turn on sprite 1, while leaving the statuses of the other sprites unchanged. We can do this with the following BASIC statement which combines an **AND** statement with an **OR** statement.

```
POKE 53269, (((PEEK(53269)) AND 223) OR 2)
```

The technique of using **PEEK** on a memory address and combining the result with bitwise logical operators, followed by a **POKE** to that same memory address is very common.

CONVERTING NUMBERS

The program below is written in BASIC. It does number conversion for you. Type it in and save it under the name "CONVERT.BAS".

To execute the program, type **RUN** and press the **RETURN** key.

The program presents you with a series of text menus. You may choose to convert a single decimal, binary or hexadecimal number. Alternatively, you may choose to convert a range of such numbers.

The program can convert numbers in the range 0 to 65535.

45GS02 Microprocessor

- **Introduction**
- **Differences to the 6502**
- **C64 CPU Memory Mapped Registers**
- **New CPU Memory Mapped Registers**
- **MEGA65 CPU Math Unit Registers**
- **MEGA65 Hypervisor Mode**

INTRODUCTION

The 45GS02 is an enhanced version of the processor portion of the CSG4510 and of the F018 “DMAgic” DMA controller used in the Commodore 65 computer prototypes. The 4510 is, in turn, an enhanced version of the 65CE02. The reader is referred to the considerable documentation available for the 6502 and 65CE02 processors for the backwards-compatible operation of the 45GS02.

This chapter will focus on the differences between the 45GS02 and the earlier 6502-class processors, and the documentation of the many built-in memory-mapped IO registers of the 45GS02.

DIFFERENCES TO THE 6502

The 45GS02 has a number of key differences to earlier 6502-class processors:

Supervisor/Hypervisor Privileged Mode

Unlike the earlier 6502 variants, the 45GS02 has a privileged mode of operation. This mode is intended for use by an operating system or type-1 hypervisor. The ambiguity between operating system and hypervisor on the MEGA65 stems from the fact that the operating system of the MEGA65 is effectively little more than a loader and task-switcher for C64 and C65 environments, i.e., effectively operating as a hypervisor, but provides only limited virtualisation of the hardware.

The key differences between normal and supervisor mode on the MEGA65, are that in supervisor mode:

- A special 16KiB memory area is mapped to \$8000 – \$BFFF, which is used to contain both the program and data of the hypervisor / supervisor program. This is normally the Hyppo program. This memory is not mappable by any means when the processor is in the normal mode (the chip-select line to it is inhibited), protecting it from accidental or malicious access.
- The 64 SYSCALL trap registers in the MEGA65 IO-mode at \$D640 – \$D67F are replaced by the virtualisation control registers. These regis-

ters allow complete control over the system, and it is their access that truly defines the privilege of the supervisor mode.

- The processor always operates at full speed (40MHz) and in the 4510 processor personality.

The Hypervisor Mode is described in more detail later in this appendix.

6502 Illegal Opcodes

The 65C02, 65CE02 and CSG4510 processors extended the original 6502 processor by using previously unallocated opcodes of the 6502 to provide additional instructions. All software that followed the official documentation of the 6502 processor will therefore work on these newer processors, possibly with different instruction timing. However, the common practice on the C64 and other home computers of using undefined opcodes (often called “illegal opcodes”, although there is no law against using them), means that many existing programs will not work on these newer processors.

To alleviate this problem the 45GS02 has the ability to switch processor personalities between the 4510 and 6502. The effect is that in 6502 mode, none of the new opcodes of the 65C02, 65CE02, 4510 or 45GS02 are available, and are replaced with the original, often strange, behaviour of the undefined opcodes of the 6502.

WARNING: This feature is incomplete and untested. Most undocumented 6502 opcodes do not operate correctly when the 6502 personality is enabled.

Read-Modify-Write Instruction Bug Compatibility

The 65CE02 processor optimised a group of instructions called the Read-Modify-Write (RMW) instructions. For such instructions, such as INC, that increments the contents of a memory location, the 6502 would read the original value and then write it back unchanged, before writing it back with the new increased value. For most purposes, this did not cause any problems. However, it turned out to be a fast way to acknowledge VIC-II interrupts, because writing the original value back (which the instruction doesn’t need to do) acknowledges the interrupt. This method is faster and uses fewer bytes than any alternative, and so became widely used in C64 software.

The problem came with the C65 with its 65CE02 derived CSG4510 that didn't do this extra write during the RMW instructions. This made the RMW instructions one cycle faster, which made software run slightly faster. Unfortunately, it also meant that a lot of existing C64 software simply won't run on a C65, unless the interrupt acknowledgement code in each program is patched to work around this problem. This is the single most common reason why many C64 games and other software titles won't run on a C65.

Because this problem is so common, the MEGA65's 45GS02 includes bug compatibility with this commonly used feature of the original 6502. It does this by checking if the target of an RMW instruction is \$D019, i.e., the interrupt status register of the VIC-II. If it is, then the 45GS02 performs the dummy write, allowing many C64 software titles to run unmodified on the MEGA65, that do not run on a C65 prototype. By only performing the dummy write if the address is \$D019, the MEGA65 maintains C64 compatibility, without sacrificing the speed improvement for all other uses of these instructions.

Variable CPU Speed

The 45GSG02 is able to run at 1MHz, 2MHz, 3.5MHz and 40MHz, to support running software designed for the C64, C128 in C64 mode, C65 and MEGA65.

Slow (1MHz – 3.5MHz) Operation

In these modes, the 45GS02 processor slows down, so that the same number of instructions per video frame are executed as on a PAL or NTSC C64, C128 in C64 mode or C65 prototype. This is to allow existing software to run on the MEGA65 at the correct speed, and with minimal display problems. The VIC-IV video controller provides cycle indication pulses to the 45GS02 that are used to keep time.

In these modes, opcodes take the same number of cycles as an 6502. However memory accesses within an instruction are not guaranteed to occur in the same cycle as on a 1MHz 6502. Normally the effect is that instructions complete faster, and the processor idles until the correct number of cycles have passed. This means that timing may be incorrect by upto 7 micro-seconds. This is not normally a problem, and even many C64 fast loaders will function correctly. For example, the GEOS(tm) Graphical Operating System for the C64 can be booted and used from a 1541 connected to the MEGA65's serial port.

However, some advanced VIC-II graphics tricks, such as Variable Screen Position (VSP) are highly unlikely to work correctly, due to the uncertainty in timing of the memory write cycles of instructions. However, in most cases such problems can be easily solved by using the advanced features of the MEGA65's VIC-IV video controller. For example, VSP is unnecessary on the MEGA65, because you can set the screen RAM address to any location in memory.

Full Speed (40MHz) Instruction Timing

When the MEGA65's processor is operating at full speed (currently 40MHz), the instruction timing no longer exactly mirrors the 6502: Instructions that can be executed in fewer cycles will do so. For example, branches are typically require fewer instructions on the 45GS02. There are also some instructions that require more cycles on the 45GS02, in particular the LDA, LDX, LDY and LDZ instructions. Those instructions typically require one additional cycle. However as the processor is running at 40MHz, these instructions still execute much more quickly than on even a C65 or C64 with an accelerator.

CPU Speed Fine-Tuning

It is also possible to more smoothly vary the CPU speed using the **SPEEDBIAS** register located at \$F7FA (55290), when MEGA65 IO mode is enabled. The default value is \$80 (128), which means no bias on the CPU speed. Higher values increase the CPU speed, with \$FF meaning 2× the expected speed. Lower values slow the processor down, with \$00 bring the CPU to a complete stand-still. Thus the speed can be varied between 0× and 2× the intended value.

This register is provided to allow tweaking the processor speed in games.

Note that this register has no effect when the processor is running at full-speed, because it only affects the way in which VIC-IV video cycle indication pulses are processed by the CPU.

Direct Memory Access (DMA)

Direct Memory Access (DMA) is a method for quickly filling, copying or swapping memory regions. The MEGA65 implements an improved version of the F018 "DMAgic" DMA controller of the C65 prototypes. Unlike on the C65 prototypes, the DMA controller is part of the CPU on the MEGA65.

Detailed information on how to use the DMA controller and these advanced features can be found in Appendix F

Accessing memory between the 64KB and 1MB points

The C65 included four ways to access memory beyond the 64KB point: three methods that are limited, specialised or both, and two general-purpose methods. We will first consider the limited methods, before documenting the general-purpose methods.

C64-Style Memory Banking

The first method, is to use the C64-style \$00/\$01 ROM/RAM banking. This method is very limited, however, as it allows only the banking in and out of the two 8KB regions that correspond to the C64 BASIC and KERNAL ROMs. These are located at \$2A000 and \$2E000 in the 20-bit C65 address space, i.e., \$002A000 and \$002E000 in the 28-bit address space of the MEGA65. It can also provide access to the C64 character ROM data at \$D000, which is located at \$2D000 in the C65 memory map, and thus \$002D0000 in the MEGA65 address space. In addition to being limited to which regions this method can access, it also only provides read-only access to these memory regions, i.e., it cannot be used to modify these memory regions.

VIC-III “ROM” Banking

Similar to the C64-style memory banking, the C65 included the facility to bank several other regions of the C65’s 128KB ROM. These are banked in and out using various bits of the VIC-III’s \$D030 register:

\$D030 Bit	Signal Name	20-bit Address	16-bit Address	Read-Write Access?
0	CRAM2K	\$1F800 - \$1FFFF, \$FF80000 - \$FF807FF	\$D800 - \$DFFF	Y
3	ROM8	\$38000 - \$39FFF	\$8000 - \$9FFF	N
4	ROMA	\$3A000 - \$3BFFF	\$A000 - \$BFFF	N
5	ROMC	\$2C000 - \$2CFFF	\$C000 - \$CFFF	N
6	CROM9	\$29000 - \$29FFF	\$D000 - \$DFFF	N

continued ...

...continued

\$D030 Bit	Signal Name	20-bit Address	16-bit Address	Read-Write Access?
7	ROME	\$3E000 - \$3FFFF	\$E000 - \$FFFF	N

The CRAM2K signal causes the normal 1KB of colour RAM, which is located at \$1F800 - \$1FBFF and is visible at \$D800 - \$DBFF, to instead be visible from \$D800 - \$DFFF. That is, the entire range \$1F800 - \$1FFFF is visible, and can be both read from and written to. Unlike on the C64, the colour RAM on the MEGA65 is always visible as 8-bit bytes. Also, on the MEGA65, the colour RAM is 32KB in size, and exists at \$FF80000 - \$FF87FFF. The visibility of the colour RAM at \$1F800 - \$1FFFF is achieved by mirroring writes to both regions when accessing the colour RAM via this mechanism.

Note that these VIC-III memory banking signals take precedence over the C64-style memory banking.

VIC-III Display Address Translator

The third specialised manner to access to memory above the 64KB point is to use the VIC-III's Display Address Translator. Use of this mechanism is documented in Appendix G.

The MAP instruction

The first general-purpose means of access to memory is the MAP instruction of the 4510 processor. The MEGA65's 45GS02 processor also supports this mechanism. This instruction divides the 64KB address of the 6502 into eight blocks of 8KB each. For each of these blocks, the block may either be accessed normally, i.e., accessing an 8KB region of the first 64KB of RAM of the system. Alternatively, each block may instead be re-mapped (hence the name of the MAP instruction) to somewhere else in the address space, by adding an offset to the address. Mapped addresses in the first 32KB use one offset, the lower offset, and the second 32KB uses another, the upper offset. Re-mapping of memory using the MAP instruction takes precedence over the C64-style memory banking, but not the C65's ROM banking mechanism.

The offsets must be a multiple of 256 bytes, and thus consist of 12 bits in order to allow an arbitrary offset in the 1MB address space of the C65. As each 8KB block in a 32KB half of memory can be either mapped or not, this requires one bit per 8KB block. Thus the processor requires 16 bits of information for each half of memory, for a total of 32 bits of information. This is achieved by setting

the A and X registers for the lower half of memory and the Y and Z registers for the upper half of memory, before executing the MAP instruction. The MAP instruction copies the contents of these registers into the processors internal registers that hold the mapping information. Note that there is no way to use the MAP instruction to determine the current memory mapping configuration, which somewhat limits its effectiveness.

See under “Using the MAP instruction to access > 1MB” for further explanation and an example.

Direct Memory Access (DMA) Controller

The C65’s F018/F018A DMA controller allows for rapid filling, copying and swapping of the contents of memory anywhere in the 1MB address space. Detailed information about the F018 DMA controller, and the MEGA65’s enhancements to this, refer to Appendix F

Flat Memory Access

Accessing memory beyond the 1MB point

The MEGA65 can support up to 256MiB of memory. This is more than the 1MiB address space of the CSG4510 on which it is based. There are several ways of performing this.

Using the MAP instruction to access > 1MB

The full address space is available to the MAP instruction for legacy C65-style memory mapping, although some care is required, as the MAP instruction must be called up to three times. The reason for this is that the MAP instruction must be called to first select which mega-byte of memory will be used for the lower and upper map regions, before it is again called in the normal way to set the memory mapping. Because between these two calls the memory mapping offset will be a mix of the old and new addresses, all mapping should be first disabled via the MAP instruction. This means that the code to re-map memory should live in the bottom 64KB of RAM or in one of the ROM-bankable regions, so that it can remain visible during the mapping process.

Failure to handle this situation properly will result in the processor executing instructions from somewhere unexpected half-way through the process,

because the routine it is executing to perform the mapping will suddenly no longer be mapped.

Because of the relative complexity of this process, and the other problems with the MAP instruction as a means of memory access, we recommend that for accessing data outside of the current memory map that you use either DMA or the flat-memory address features of the 45GS02 that are described below. Indeed, access to the full address space via the MAP instruction is only provided for completeness.

To give a very simple example of how the MAP instruction can be used to map an area of memory from the expanded address space, the following program maps the ethernet frame buffer from its natural location at \$FFDE8000 to appear at \$6800. To keep the example as simple as possible, we assume that the code is running from in the bottom 64KB of RAM, and not in the region between \$6000 - \$8000.

As the MAP instruction normally is only aware of the C65-style 20-bit addresses, the MEGA65 extension to the instruction must be used to set the upper 8 bits of the 28-bit MEGA65 addresses, i.e., which mega-byte of address space should be used for the address translation. This is done by setting the X register to \$0F when setting the mega-byte number for the lower-32KB of the C64-style 64KB address space. This does not create any incompatibility with any sensible use of the MAP instruction on a C65, because this value indicates that none of the four 8KB memory blocks will be re-mapped, but at the same time specifies that the upper 4 bits of the address offset for re-mapped block is the non-zero value of \$F. The mega-byte number is then specified by setting the A register.

The same approach applies to the upper 32KB, but using the Z and Y registers instead of the X and A registers. However, in this case, we do not need to re-map the upper 32KB of memory in this example, we will leave the Z and Y registers set to zero. We must however set X and A to set the mega-byte number for the lower-32KB to \$FF. Therefore A must have the value \$FF. To set the lower 20-bits of the address offset we use the MAP instruction a second time, this time using it in the normal C65 manner. As we want to remap \$6800 to \$FFDE800, and have already dealt with the \$FFxxxx offset via the mega-byte number, we need only to apply the offset to make \$6800 point to \$DE800. $\$DE800 - \$6800 = \$D8000$. As the MAP instruction operates with a mapping granularity of 256 bytes = \$100, we can drop the last two digits from \$D8000 to obtain the MAP offset of \$D80. The lower 8-bits, \$80, must be loaded into the A register. The upper 4-bits, \$D, must be loaded into the low-nibble of the X register. As we wish to apply the mapping to only the fourth of the 8KB blocks that make up the lower 32KB half of the C64 memory

map, we must set the 4th bit of the upper nybl. That is, the upper nybl must be set to %1000, i.e., \$8. Therefore the X register must be loaded with \$8D. Thus we yield the complete example program:

```
; Map ethernet registers at $6000 - $7FFF

; Ethernet controller really lives $FFDE000 - $FFDEFFF, so select $FF megabyte set
lda #$ff
ldx #$0f
ldy #$00
ldz #$00
map

; now enable mapping of $DE000-$DFFFF at $6000
; MAPs are offset based, so we need to subtract $6000 from the target address
; $DE000 - $6000 = $D8000
lda #$80
ldx #$8d
ldy #$00
ldz #$00
map
eom

; Ethernet buffer now visible at $6800 - $6FFF
```

Note that the EOM (End Of Mapping) instruction (which is the same as NOP on a 6502, i.e., opcode \$EA) was only supplied after the last MAP instruction, to make sure that no interrupts could occur while the memory map contained mixed values with the mega-byte number set, but the lower-bits of the mapping address had not been updated.

No example in BASIC for the MAP instruction is possible, because the MAP is an machine code instruction of the 4510 / 45GS02 processors.

Flat-Memory Access

The 45GS02 makes it easy to read or write a byte from anywhere in memory by allowing the Zero-Page Indirect addressing mode to use a 32-bit pointer instead of the normal 16-bit pointer. This is accomplished by using the Z-indexed Zero-Page Indirect Addressing Mode for the access, and having the

instruction directly preceded by a NOP instruction (opcode \$EA). For example:

```
NOP
LDA ($45),Z
```

Would read the four bytes of Zero-Page memory at \$45 - \$48 to form a 32-bit memory address, and add the value of the Z register to this to form the actual address that will be read from. The byte order in the address is the same as the 6502, i.e., the right-most (least significant) byte of the address will be read from the first address (\$45 in this case), and so on, until the left-most (most significant) byte will be read from \$48. For example, to read from memory location \$12345678, the contents of memory beginning at \$45 should be 78 56 43 12.

This method is much more efficient and also simpler than either using the MAP instruction or the DMA controller for single memory accesses, and is what we generally recommend. The DMA controller can be used for moving/filler larger regions of memory. We recommend the MAP instruction only be used for banking code, or in rare situations where extensive access to a small region of memory is required, and the extra cycles of reading the 32-bit addresses is problematic.

Virtual 32-bit Register

The 45GS02 allows the use of its four general purpose registers, A, X, Y and Z as a single virtual 32-bit register. This can greatly simplify and speed up many common operations, and help avoid many common programming errors. For example, adding two 16-bit or 32-bit values can now be easily accomplished with something like:

```
; Clear carry before performing addition, as normal
CLC
; Prefix an instruction with two NEG instructions to select virtual 32-bit register
NEG
NEG
LDA $1234 ; Load the contents of $1234-$1237 into A,X,Y and Z respectively
; And again, for the addition
NEG
NEG
```

```

ADC $1238 ; Add the contents of $1238-$123B
; The result of the addition is now in A, X, Y and Z.
; And can be written out in whole or part

; To write it all out, again, we need the NEG + NEG prefix
NEG
NEG
STA $123C ; Write the whole out to $123C-$123F

; Or to write out the bottom bytes, we can just write the contents of A and X
STA $1240
STX $1241

```

This approach works with the LDA, STA, ADC, SBC, CMP, EOR, AND, ORA, ASL, LSR, ROL, ROR, INC and DEC instructions. It also works with any addressing mode. Indexed addressing modes, where X, Y or Z are added to the address should be used with care, because these registers may in fact be holding part of a 32-bit value. The special case is the Zero-Page Indirect Z-Indexed addressing mode: In this case the Z register is NOT added to the target address, as would normally be the case. This is to allow the virtual 32-bit register to be able to be used with flat-memory access with the combined prefix of NEG NEG NOP before the instruction to allow accessing a 32-bit value anywhere in memory in a single instruction.

Note that the virtual 32-bit register cannot be used in immediate mode, i.e., to load a constant into the four general purpose registers. This is to avoid problems with variable length instructions. Also, it would not save any bytes compared to LDA #\$nn ... LDZ #\$nn, and would be no faster.

C64 CPU MEMORY MAPPED REGISTERS

- **MULTINB** Multiplier input A (18 bit)
- **MULTOUT** 48-bit output of $MULTINA \times MULTINB$
- **RESERVED** Reserved
- **UNIT0INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 0.
- **UNIT0INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 0.
- **UNIT0OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 0
- **UNIT10INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 10.
- **UNIT10INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 10.
- **UNIT10OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit A
- **UNIT11INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 11.
- **UNIT11INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 11.
- **UNIT11OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit B
- **UNIT12INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 12.
- **UNIT12INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 12.

- **UNIT12OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit C
- **UNIT13INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 13.
- **UNIT13INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 13.
- **UNIT13OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit D
- **UNIT14INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 14.
- **UNIT14INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 14.
- **UNIT14OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit E
- **UNIT15INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 15.
- **UNIT15INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 15.
- **UNIT15OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit F
- **UNIT1INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 1.
- **UNIT1INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 1.
- **UNIT1OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 1
- **UNIT2INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 2.
- **UNIT2INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 2.
- **UNIT2OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 2
- **UNIT3INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 3.

- **UNIT3INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 3.
- **UNIT3OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 3
- **UNIT4INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 4.
- **UNIT4INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 4.
- **UNIT4OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 4
- **UNIT5INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 5.
- **UNIT5INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 5.
- **UNIT5OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 5
- **UNIT6INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 6.
- **UNIT6INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 6.
- **UNIT6OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 6
- **UNIT7INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 7.
- **UNIT7INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 7.
- **UNIT7OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 7
- **UNIT8INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 8.
- **UNIT8INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 8.
- **UNIT8OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 8

- **UNIT9INA** Select which of the 16 32-bit math registers is input A for Math Function Unit 9.
- **UNIT9INB** Select which of the 16 32-bit math registers is input B for Math Function Unit 9.
- **UNIT9OUT** Select which of the 16 32-bit math registers receives the output of Math Function Unit 9
- **WREN** Enable setting of math registers (must normally be set)

MEGA65 HYPERVISOR MODE

Reset

On power-up or reset, the MEGA65 starts up in hypervisor mode, and expects to find a program in the 16KiB hypervisor memory, and begins executing instructions at address \$8100. Normally a JMP instruction will be located at this address, that will jump into a reset routine. That is, the 45GS02 does not use the normal 6502 reset vector. It's function is emulated by the Hyppo hypervisor program, which fetches the address from the 6502 reset vector in the loaded client operating system when exiting hypervisor mode.

The hypervisor memory is automatically mapped on reset to \$8000 - \$BFFF. This special memory is not able to mapped or in anyway accessed, except when in hypervisor mode. This includes from the serial monitor/debugger interface. This is to protect it from accidental or malicious access from a guest operating system.

Entering / Exiting Hypervisor Mode

Entering the Hypervisor occurs whenever any of the following events occurs:

- **Power-on** When the MEGA65 is first powered on.
- **Reset** If the reset line is lowered, or a watch-dog triggered reset occurs.
- **SYSCALL register accessed** The registers \$D640 - \$D67F in the MEGA65 IO context trigger SYSCALLs when accessed. This is intended to be the mechanism by which a client operating system or process requests the attention of the hypervisor or operating system.

- **Page Fault** On MEGA65s that feature virtual memory, a page fault will cause a trap to hypervisor mode.
- **Certain keyboard events** Pressing the **RESTORE** key for >0.5 seconds, or the **ALT** + **TAB** key combination traps to the hypervisor. Typically the first is used to launch the freeze menu and the second to toggle the display of debug interface.
- **Accessing virtualised IO devices** For example, if the F011 (internal 3.5" disk drive controller) has been virtualised, then attempting to read or write sectors using this device will cause traps to the hypervisor.
- **Executing an instruction that would lock up the CPU** A number of undocumented opcodes on the 6502 will cause the CPU to lockup. On the MEGA65, instead of locking up, the computer will trap to the hypervisor. This could be used to implement alternative instruction behaviours, or simply to tell the user that something bad has happened.
- **Certain special events** Some devices can generate hypervisor-level interrupts. These are implemented as traps to the hypervisor.

The 45GS02 handles all of these in a similar manner internally:

1. The SYSCALL or trap address is calculated, based on the event.
2. The contents of all CPU registers are saved into the virtualisation control registers.
3. The hypervisor mode memory layout is activated, the CPU decimal flag and special purpose registers are all set to appropriate values. The contents of the A,X,Y and Z and most other CPU flags are preserved, so that they can be accessed from the hypervisor's SYSCALL/trap handler routine, without having to load them, thus saving a few cycles for each call.
4. The hypervisor-mode flag is asserted, and the programme counter (PC) register is set to the computed address.

All of the above happens in one CPU cycle, i.e., in 25 nano-seconds. Returning from a SYSCALL or trap consists simply of writing to \$D67F, which requires 125 nano-seconds, for a total overhead of 150 nano-seconds. This gives the MEGA65 SYSCALL performance rivaling – even beating – even the fastest modern computers, where the system call latency is typically hundreds to tens of thousands of cycles [1].

Hypervisor Memory Layout

The hypervisor memory is 16KiB in size. The first 512 bytes are reserved for SYSCALL and system trap entry points, with four bytes for each. For example, the reset entry point is at \$8100 - \$8100 + 3 = \$8100 - \$8103. This allows 4 bytes for an instruction, typically a JMP instruction, followed by a NOP to pad it to 4 bytes.

The full list of SYSCALLs and traps is:

HEX	DEC	Name	Description
8000	32768	SYSCALL00	Syscall 0 entry point
8004	32772	SYSCALL01	Syscall 1 entry point
8008	32776	SYSCALL02	Syscall 2 entry point

HEX	DEC	Name	Description
8108	33032	RESTORKEY	Restore-key long press trap entry point
810C	33036	ALT+TABKEY	ALT+TAB trap entry point
8110	33040	VF011RD	F011 virtualised disk read trap entry point
8114	33044	VF011WR	F011 virtualised disk write trap entry point
8118	33048	BREAKPT	CPU breakpoint encountered
811C - 81FB	33048 - 33275	RESERVED	Reserved traps point entry
81FC	33276	CPUKIL	KIL instruction in 6502-mode trap entry point

The remainder of the 16KiB hypervisor memory is available for use by the programmer, but xwill typically use the last 512 bytes for the stack and zero-page, giving an overall memory map as follows:

HEX	DEC	Description
8000 - 81FF	32768 - 33279	SYSCALL and trap entry points
8200 - BDFE	33280 - 48639	Available for hypervisor or operating system program
8E00 - BEFF	48640 - 48895	Processor stack for hypervisor or operating system
8F00 - BFFF	48896 - 49151	Processor zero-page storage for hypervisor or operating system

The stack is used for holding the return address of function calls. The zero-page storage is typically used for holding variables and other short-term storage, as is customary on the 6502.

- **ASCFast** Hypervisor enable ASC/DIN CAPS LOCK key to enable/disable CPU slow-down in C64/C128/C65 modes
- **CARTEN** Hypervisor enable /EXROM and /GAME from cartridge
- **CPUFast** Hypervisor force CPU to 48MHz for userland (userland can override via POKE0)
- **DMADSTMB** Hypervisor DMAgic destination MB

- **DMALADDR** Hypervisor DMAGic list address bits 0–7
- **DMASRCMB** Hypervisor DMAGic source MB
- **ENTEREXIT** Writing trigger return from hypervisor
- **EXSID** 0=Use internal SIDs, 1=Use external(1) SIDs
- **F4502** Hypervisor force CPU to 4502 personality, even in C64 IO mode.
- **GEORAMBASE** Hypervisor GeoRAM base address (x MB)
- **GEORAMMASK** Hypervisor GeoRAM address mask (applied to GeoRAM block register)
- **HICKED** Hypervisor already-upgraded bit (writing sets permanently)
- **JMP32EN** Hypervisor enable 32-bit JMP/JSR etc
- **MAPHI** Hypervisor MAPHI register storage (high bits)
- **MAPHIMB** Hypervisor MAPHI mega-byte number register storage
- **MAPLO** Hypervisor MAPLO register storage (high bits)
- **MAPLOMB** Hypervisor MAPLO mega-byte number register storage
- **MATRIXEN** Enable composited Matrix Mode, and disable UART access to serial monitor.
- **PCH** Hypervisor PC-high register storage
- **PCL** Hypervisor PC-low register storage
- **PFLAGS** Hypervisor P register storage
- **PIRQ** Hypervisor flag to indicate if an IRQ is pending on exit from the hypervisor / set 1 to force IRQ/NMI deferral for 1,024 cycles on exit from hypervisor.
- **PNMI** Hypervisor flag to indicate if an NMI is pending on exit from the hypervisor.
- **PORT00** Hypervisor CPU port \$00 value
- **PORT01** Hypervisor CPU port \$01 value
- **REGA** Hypervisor A register storage
- **REGB** Hypervisor B register storage
- **REGX** Hypervisor X register storage
- **REGZ** Hypervisor Z register storage

- **ROMPROT** Hypervisor write protect C65 ROM \$20000-\$3FFFF
- **SPH** Hypervisor SPH register storage
- **UARTDATA** (write) Hypervisor write serial output to UART monitor
- **VFLOP** 1=Virtualise SD/Floppy access (usually for access via serial debugger interface)
- **VICMODE** VIC-II/VIC-III/VIC-IV mode select
- **WATCHDOG** Hypervisor watchdog register: writing any value clears the watch dog

Programming for Hypervisor Mode

The easiest way to write a program for Hypervisor Mode on the MEGA65 is to use KickC, which is a special version of C made for writing programs for 6502-class processors. The following example programs are from KickC's supplied examples. KickC produces very efficient code, and directly supports the MEGA65's hypervisor mode quite easily through the use of a linker definition file with the following contents:

```
.file [name="%0.bin", type="bin", segments="XMega65Bin"]
.segmentdef XMega65Bin [segments="Syscall, Code, Data, Stack, Zeropage"]
.segmentdef Syscall [start=$8000, max=$81ff]
.segmentdef Code [start=$8200, min=$8200, max=$bdcff]
.segmentdef Data [startAfter="Code", min=$8200, max=$bdcff]
.segmentdef Stack [min=$be00, max=$bfff, fill]
.segmentdef Zeropage [min=$bf00, max=$bfff, fill]
```

This file instructs KickC's assembler to create a 16KiB file with the 512 byte SYSCALL/trap entry point region at the start, followed by code and data areas, and then the stack and zero-page areas. It enforces the size and location of these fields, and will give an error during compilation if anything is too big to fit.

With this file in place, you can then create a KickC source file that provides data structures for the SYSCALL/trap table, e.g.:

```
// XMega65 Kernal Development Template
// Each function of the kernal is a no-args function
// The functions are placed in the SYSCALLS table surrounded by JMP and NOP
```

```

import "string"

// Use a linker definition file (put the previous listing into that file)
#pragma link("mega65hyper.ld")

// Some definitions of addresses and special values that this program uses
const char* RASTER = 0xd012;
const char* VIC+MEMORY = 0xd018;
const char* SCREEN = 0x0400;
const char* BGCOL = 0xd021;
const char* COLS = 0xd800;
const char BLACK = 0;
const char WHITE = 1;

// Some text to display
char[] MESSAGE = "hello world!";

void main() {
    // Initialize screen memory, and select correct font
    *VIC+MEMORY = 0x14;
    // Fill the screen with spaces
    memset(SCREEN, ' ', 40*25);
    // Set the colour of every character on the screen to white
    memset(COLS, WHITE, 40*25);
    // Print the "hello world!" message
    char* sc = SCREEN+40; // Display it one line down on the screen
    char* msg = MESSAGE; // The message to display
    // A simple copy routine to copy the string
    while(*msg) {
        *sc++ = *msg++;
    }
    // Loop forever showing two white lines as raster bars
    while(true) {
        if(*RASTER==54 || *RASTER==66) {
            *BGCOL = WHITE;
        } else {
            *BGCOL = BLACK;
        }
    }
}

```

```

    }
}

// Here are a couple sample SYSCALL handlers that just display a character on the
void syscall1() {
    *(SCREEN+79) = ')';
}

void syscall2() {
    *(SCREEN+78) = '<';
}

// Now we select the SYSCALL segment to hold the SYSCALL/trap entry point table.
#pragma data=seg(Syscall)

// The structure of each entry point is JMP (handler address) + NOP.
// We have a char (xjmp) to hold the opcode for the JMP instruction,
// and then put the address of the SYSCALL/trap handler in the next
// two points as a pointer, and end with the NOP instruction opcode.
struct SysCall {
    char xjmp;           // Holds $4C, the JMP $nnnn opcode
    void()* syscall;     // Holds handler address, will be the target of the JMP
    char xnop;          // Holds $EA, the NOP opcode
};

// To save writing 0x4C and 0xEA all the time, we define them as constants
const char JMP = 0x4c;
const char NOP = 0xea;

// Now we can have a nice table of up to 64 SYSCALL handlers expressed
// in a fairly readable and easy format.
// Each line is an instance of the struct SysCall from above, with the JMP
// opcode value, the address of the handler routine and the NOP opcode value.
export struct SysCall[] SYSCALLS = {
    { JMP, &syscall1, NOP },
    { JMP, &syscall2, NOP }
};

// In this example we had only two SYSCALLs defined, so rather than having

```

```
// another 62 lines, we can just ask KickC to make the TRAP table begin
// at the next multiple of $100, i.e., at $8100.
export align(0x100) struct SysCall[] SYSCALL+RESET = {
    { JMP, &main, NOP }
};
```

If you save the first listing into a file called mega65hyper.ld, and the second into a file called mega65hyper.kc, you can then compile them using KickC with a command like:

```
kickc -a mega65hyper
```

It will then produce a file called mega65hyper.bin, which you can then try out on your MEGA65, or run in the Xmega65 emulator with a command like:

```
xmega65 -kickup mega65hyper.bin
```

APPENDIX

F

F018-Compatible Direct Memory Access (DMA) Controller

- **F018 “DMAgic” DMA Controller**
- **MEGA65 DMA Controller Extensions**

The MEGA65 includes an F018/F018A backward-compatible DMA controller. Unlike in the C65, where the DMA controller exists as a separate chip, it is part of the 45GS02 processor in the MEGA65. However, as the use of the DMA controller is a logically separate topic, it is documented separately in this appendix.

The MEGA65's DMA controller provides several important improvements over the F018/F018A DMA chips of the C65:

- **Speed** The MEGA65 performs DMA operations at 40MHz, allowing filling 40MiB or copying 20MiB per second. For example, it is possible to copy a complete 8KiB C64-style bitmap display in about 200 micro-seconds, equivalent to less than four raster lines!
- **Large Memory Access** The MEGA65's DMA controller allows access to all 256MiB of address space.
- **Texture Copying Support** The MEGA65's DMA controller can do fractional address calculations to support hardware texture scaling, as well as address striding, to make it possible in principle to simultaneously scale-and-draw a texture from memory to the screen. This would be useful, should anyone be crazy enough to try to implement a Wolfenstein or Doom style-game on the MEGA65.
- **Transparency/Mask Value Support** The MEGA65's DMA controller can be told to ignore a special value when copying memory, leaving the destination memory contents unchanged. This allows masking of transparent regions when performing a DMA copy, which considerably simplifies blitting of graphics shapes.

Per-Job Option List A number of options can be configured for each job in a chained list of DMA jobs, for example, selecting F018 or F018B mode, changing the transparency value, fractional address stepping or the source or destination memory region.

F018 “DMAGIC” DMA CONTROLLER

HEX	DEC	Signal	Description
D700	55040	ADDRLSB-TRIG	DMAGic DMA list address LSB, and trigger DMA (when written)
D701	55041	ADDRMSB	DMA list address high byte (address bits 8 - 15).

continued ...

...continued

HEX	DEC	Signal	Description
D702	55042	ADDRBANK	DMA list address bank (address bits 16 – 22). Writing clears \$D704.

MEGA65 DMA CONTROLLER EXTENSIONS

HEX	DEC	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
D703	55043	–							EN018B
D704	55044	ADDRMB							
D705	55045	ETRIG							
D70E	55054	ADDRLSB							

- **ADDRLSB** DMA list address low byte (address bits 0 – 7) WITHOUT STARTING A DMA JOB (used by Hypervisor for unfreezing DMA-using tasks)
- **ADDRMB** DMA list address mega-byte
- **EN018B** DMA enable F018B mode (adds sub-command byte)
- **ETRIG** Set low-order byte of DMA list address, and trigger Enhanced DMA job (uses DMA option list)

APPENDIX

VIC-IV Video Interface Controller

- **Features**
- **VIC-II/III/IV Register Access Control**
- **Video Output Formats, Timing
and Compatability**
- **Memory Interface**
- **Hot Registers**
- **New Modes**
- **Sprites**

- **VIC-II / C64 Registers**
- **VIC-III / C65 Registers**
- **VIC-IV / MEGA65 Specific Registers**

FEATURES

The VIC-IV is a fourth generation Video Interface Controller developed especially for the MEGA65, and featuring very good backwards compatibility with the VIC-II that was used in the C64, and the VIC-III that was used in the C65. The VIC-IV can be programmed as though it were either of those predecessor systems. In addition it supports a number of new features. It is easy to mix older VIC-II/III features with the new VIC-IV features, making it easy to transition from the VIC-II or VIC-III to the VIC-IV, just as the VIC-III made it easy to transition from the VIC-II. Some of the new features and enhancements of the VIC-IV include:

- **Direct access to 384KB RAM** (up from 16KB/64KB with the VIC-II and 128KB with the VIC-III).
- Support for **32KB of 8-bit Colour/Attribute RAM** (up from 2KB on the VIC-III), to support very large screens.
- **HDTV 720×576 / 800×600 native resolution** at both 50Hz and 60Hz for **PAL and NTSC**, with **VGA and digital video** output.
- **81MHz pixel clock** (up from 8MHz with the VIC-II/III), which enables a wide range of new features.
- New 16-colour (16×8 pixels per character cell) and 256-colour (8×8 pixels per character cell) **full-colour character modes**.
- Support for upto **8,192 unique characters in a character set**.
- **Four 256-colour palette banks** (versus the VIC-III's single palette bank), each supporting **23-bit colour depth** (versus the VIC-III's 12-bit colour depth), and which can be rapidly alternated to create even more colourful graphics than is possible with the VIC-III.
- Screen, bitmap, colour and character data can be positioned at any **address with byte-level granularity** (compared with fixed 1KB - 16KB boundaries with the VIC-II/III)
- **Virtual screen dimensioning**, which combined with byte-level data position granularity provides effective **hardware support for scrolling and panning in both X and Y directions**.
- **New sprite modes**: Bitplane modification, **full-colour** (15 foreground colours + transparency) and tiled modes, allowing a wide variety of new and exciting sprite-based effects

- The ability to stack sprites in a bit-planar manner to produce **sprites with upto 256 colours**. n
- Sprites can use 64 bits of data per raster line, allowing **sprites to be 64 pixels wide** when using VIC-II/III mono/multi-colour mode, or 16 pixels wide when using the new VIC-IV full-colour sprite mode.
- **Sprite tile mode**, which allows a sprite to be repeated horizontally across an entire raster line, allowing sprites to be used to create animated backgrounds in a memory-efficient manner.
- Sprites can be configured to use a **separate 256-colour palette** to that used to draw other text and graphics, allowing for a more colourful display.
- **Super-extended attribute mode** which uses two screen RAM bytes and two colour RAM bytes per character mode, which supports a wide variety of new features including **alpha-blending/anti-aliasing, hardware kerning/variable-width characters**, hardware horizontal/vertical flipping, alternate palette selection and other powerful features that make it easy to create highly dynamic and colourful displays.
- **Raster-Rewrite Buffer** which allows **hardware-generated pseudo-sprites**, similar to “bobs” on Amiga(tm) computers, but with the advantage that they are rendered in the display pipeline, and thus do not need to be undrawn and redrawn to animate them.
- **Multiple 8-bit colour playfields** are also possible using the Raster-Rewrite Buffer.

In short, the VIC-IV is a powerful evolution of the VIC-II/III, while retaining the character and distinctiveness of the VIC-series of video controllers.

For a full description of the additional registers that the VIC-IV provides, as well as documentation of the legacy VIC-II and VIC-III registers, refer to the corresponding sections of this appendix. The remainder of the appendix will focus on describing the capabilities and use of many of the VIC-IV’s new features.

VIC-II/III/IV REGISTER ACCESS CONTROL

Because the new features of the VIC-IV are all extensions to the existing VIC-II/III designs, there is no concept of having to select which mode in which

the VIC-IV will operate: It is always in VIC-IV mode. However, for backwards compatibility with software, the many additional registers of the VIC-IV can be hidden, so that it appears to be either a VIC-II or VIC-III. This is done in the same manner that the VIC-III uses to hide its new features from legacy VIC-II software.

The mechanism is the VIC-III write-only KEY register (\$D02F, 53295 decimal). The VIC-III by default conceals its new features until a “knock” sequence is performed. This consists of writing two special values one after the other to \$D02F. The following table summarises the knock sequences supported by the VIC-IV, and indicates which are VIC-IV specific, and which are supported by the VIC-III:

First Value Hex (Decimal)	Second Value Hex (Decimal)	Effect	VIC-IV Specific?
\$00 (0)	\$00 (0)	Only VIC-II registers visible (all VIC-III and VIC-IV new registers are hidden)	No
\$A5 (165)	\$96 (150)	VIC-III new registers visible	No
\$47 (71)	\$53 (83)	Both VIC-III and VIC-IV new registers visible	Yes
\$45 (69)	\$54 (84)	No VIC-II/III/IV registers visible. 45E100 ethernet controller buffers are visible instead	Yes

Detecting VIC-II/III/IV

Detecting which generation of the VIC-II/III/IV a machine is fitted with can be important for programs that support only particular generations, or that wish to vary their graphical display based on the capabilities of the machine. While there are many possibilities for this, the following is a simple and effective method. It relies on the fact that the VIC-III and VIC-IV do not repeat the VIC-II registers throughout the IO address space. Thus while \$D000 and \$D100 are synonymous when a VIC-II is present (or a VIC-III/IV is hiding their additional registers), this is not the case when a VIC-III or VIC-IV is making all of its registers visible. Therefore presence of a VIC-III/IV can be determined by testing whether these two locations are aliases for the same register, or

represent separate registers. The detection sequence consists of using the KEY register to attempt to make either VIC-IV or VIC-III additional registers visible. If either succeeds, then we can assume that the corresponding generation of VIC is installed. As the VIC-IV supports the VIC-III KEY knocks, we must first test for the presence of a VIC-IV. Also, we assume that the MEGA65 starts in VIC-IV mode, even when running C65 BASIC. Thus the test can be done in BASIC from either C64 or C65 mode as follows:

```
0 REM IN C65 MODE WE CANNOT SAFELY WRITE TO 53295, SO WE TEST A DIFFERENT WAY
10 IF PEEK(53272) AND 32 THEN GOTO 65
20 POKE53248,1:POKE53295,71:POKE53295,83
30 POKE53248+256,0:IFPEEK(53248)=1THENPRINT"VIC-IV PRESENT":END
40 POKE53248,1:POKE53295,165:POKE53295,150
50 POKE53248+256,0:IFPEEK(53248)=1THENPRINT"VIC-III PRESENT":END
60 PRINT "VIC-II PRESENT": END

65 REM WE ASSUME WE HAVE A C65 HERE
70 V1=PEEK(53248+80):V2=PEEK(53248+80):V3=PEEK(53248+80)
80 IF V1<V2 OR V1<V3 OR V2<V3 THEN PRINT "VIC-IV PRESENT":END
90 GOTO 40
```

As the MEGA65 is the only C64-class computer that is fitted with a VIC-IV, this can be used as a *de facto* test for the presence of a MEGA65 computer. Detection of a VIC-III can be similarly be reasonably assumed to indicate the presence of a C65.

VIDEO OUTPUT FORMATS, TIMING AND COMPATABILITY

The VIC-IV was designed for use in the MEGA65 and related systems, including the MEGAPhone family of portable devices. The VIC-IV supports both VGA and digital video output, using a connector for the digital video that accepts most cables intended for connecting HDMI(tm) compatible devices. It also supports parallel digital video output suitable for driving LCD display panels. Considerable care has been taken to create a common video front-end that supports these three output modes.

For simplicity and accuracy of frame timing for legacy software, the video format is normally based on the HDTV PAL and NTSC 720×576/480 (576p

and 480p) modes using a 27MHz output pixel clock. This is ideal for digital video and LCD display panels. However not all VGA displays support these modes, especially 720×576 at 50Hz.

In terms of VIC-II and VIC-III backwards compatibility, this display format has several effects that do not cause problems for most programs, but can cause some differences in behaviour:

1. Because VIC-IV display is progressive rather than interlaced, two physical raster lines are produced for each logical VIC-II or VIC-III raster line. This means that there are either 63 or 65 cycles per logical double raster, rather than per physical 576p/480p physical raster. This can cause some minor visual artefacts, when programs make assumptions about where on a horizontal line the VIC is drawing when, for example, the border or screen colour is changed.
2. The VIC-IV does not follow the behaviour of the VIC-III, which allowed changes in video modes, e.g., between text and bitmap mode, on characters. Nor does it follow the VIC-II's policy of having such changes take effect immediately. Instead, the VIC-IV applies changes at the start of each raster line. This can cause some minor artefacts.
3. The VIC-IV uses a single-raster rendering buffer which is populated using the VIC-IV's internal 81MHz pixel clock, before being displayed using the 27MHz output pixel clock. This means that a raster lines display content tends to be rendered much earlier in a raster line than on either the VIC-II or VIC-III. This can cause some artefacts with displays, particularly in demos that rely on specific behaviour of the VIC-II at particular cycles in a raster line, for example for effects such as VSP or FLI. At present, such effects are unlikely to display correctly on the current revision of the VIC-IV. Improved support for these features is planned for a future revision of the VIC-IV.
4. The 1280×200 and 1280×400 display modes of the VIC-III are not currently supported, as they cannot be meaningfully displayed on any modern monitor, and no software is known to support or use this feature.

Frame Timing

Frame timing is designed to match that of the 6502 + VIC-II combination of the C64. Both PAL and NTSC timing is supported, and the number of cycles per logical raster line, the number of raster lines per frame, and the number of cycles per frame are all adjusted accordingly. To achieve this, the VIC-IV ordinarily uses HDTV 576p 50Hz (PAL) and 480p 60Hz (NTSC) video modes,

with timing tweaked to be as close as possible to double-scan PAL and NTSC composite TV modes as used by the VIC-II.

The VIC-IV produces 1MHz timing impulses which are used by the 45GS02 processor, so that the correct effective frequency is provided when operating at the 1MHz, 2MHz and 3.5MHz C64, C128 and C65 compatibility modes. This allows the single machine to switch between accurate PAL and NTSC CPU timing, as well as video modes.

XXX - Diagrams showing VIC-IV PAL / NTSC mode frame timings

As these HDTV video modes are not supported by all VGA monitors, a compatibility mode is included that provides a 640×480 VGA-style mode. However, as the pixel clock of the MEGA65 is fixed at 27MHz, this mode runs at 63Hz. Nonetheless, this should work on the vast majority of VGA monitors. There should be no problem with the PAL / NTSC modes when using the digital video output of the MEGA65.

To determine whether the MEGA65 is operating in PAL or NTSC, check the PALNTSC signal (bit 7 of \$D06F, 53359 decimal). If this bit is set, then the machine is operating in NTSC mode, and clear if operating in PAL mode. This bit can be modified to change between the modes, e.g.:

```
10 IFPEEK(53272)<32THENPOKE53295,ASC("G"):POKE53295,ASC("S"):REM ENABLE C65+MEGA65
20 NTSC=PEEK(53359)AND128
30 IFNTSCTHENPRINT"MEGA65 IS IN NTSC MODE"
40 IFNTSC=0THENPRINT"MEGA65 IS IN PAL MODE"
50 INPUT"SWITCH MODES (Y/N)? ",A$
60 IFA$="Y"THENPOKE53359,PEEK(53359)+128-NTSC
70 NTSC=PEEK(53359)AND128
80 IFNTSCTHENPRINT"MEGA65 IS NOW IN NTSC MODE"
90 IFNTSC=0THENPRINT"MEGA65 IS NOW IN PAL MODE"
```

MEMORY INTERFACE

The VIC-IV supports upto 64KB of colour RAM and, in principle, 16MB of direct access RAM for video data. However in typical installations 32KB of colour RAM and either 384KB of addressable RAM is present. In MEGA65 systems, the second 128KB of RAM is typically used to hold a C65-compatible ROM, leaving 256KB available, unless software is written to avoid the need to use C65 ROM routines, in which case all 384KB can be used.

The VIC-IV supports all legacy VIC-II and VIC-III methods for accessing this RAM, including the VIC-II's use of 16KB banks, and the VIC-III's Display Address Translator (DAT). This additional memory can be used for character and bitmap displays, as well as for sprites. However, the VIC-III bitplane modes remain limited to using only the first 128KB of RAM, as the VIC-IV does not enhance the bitplane mode.

Relocating Screen Memory

To use the additional memory for screen RAM, the screen RAM start address can be adjusted to any location in memory with byte-level granularity by setting the SCRNPTR registers (\$D060 - \$D063, 53344 - 53347 decimal). For example, to set the screen memory to address 12345:

```
IFPEEK(53272)<32THENPOKE53295,ASC("G"):POKE53295,ASC("S"):REM ENABLE C65+MEGA65
POKE53344+0,69:POKE53344+1,35:POKE53344+2,1
```

Relocating Character Generator Data

The location of the character generator data can also be set with byte-level precision via the CHARPTR registers at \$D068 - \$D06A (53352 - 53354 decimal). As usual, the first of these registers holds the lowest-order byte, and the last the highest-order byte. The three bytes allow for placement of character data anywhere in the first 16MB of RAM. For systems with less than 16MB of RAM accessible by the VIC-IV, the upper address bits should be zero.

For example, to indicate that character generator data should be sourced beginning at \$41200 (266752 decimal), the following could be used. Note that the AND binary operator only works with arguments between 0 and 65,535. Therefore we first subtract $4 \times 65,536 = 262,144$ from the address (the 4 is determined by calculating $\text{INT}(266752/65536)$), before we use the AND operator to compute the lower part of the address:

```
IFPEEK(53272)<32THENPOKE53295,ASC("G"):POKE53295,ASC("S"):REM ENABLE C65+MEGA65
POKE53352,(266752-INT(266752/65536)*65536)AND255
POKE53353,INT((266752-INT(266752/65536)*65536)/256)
```

Relocating Colour / Attribute RAM

The area of colour RAM being used can be similarly set using the COLPTR registers (\$D064 – \$D065, 53348 – 53349 decimal). That is, the value is an offset from the start of the colour / attribute RAM. This is because, like on the C64, the colour / attribute RAM of the MEGA65 is a separate memory component, with its own dedicated connection to the VIC-IV. By default, the COLPTRs are set to zero, which replicates the behaviour of the VIC-II/III. To set the display to use the colour / attribute RAM beginning at offset 4000, one could use something like:

```
IFPEEK(53272)<32THENPOKE53295,ASC("G"):POKE53295,ASC("S"):REM ENABLE C65+MEGA65
POKE53348,4000 AND 255
POKE53349,INT(4000/256)
```

Relocating Sprite Pointers and Images

The location of the sprite pointers can also be moved, and sprites can be made to have their data anywhere in first 4MB of memory. This is accomplished by first setting the location of the sprite pointers by setting the SPRPTRADR registers (\$D06C – \$D06E, 53356 – 53358 decimal, but note that only the bottom 7 bits of \$D06E are used, as the highest bit is used for the SPRPTR16 signal). This allows the list of eight sprite pointers to be moved from the end of screen RAM to an arbitrary location in the first 8MB of RAM. To allow sprites themselves to be located anywhere in the first 4MB of RAM, the SPRPTR16 bit in \$D06E must be set. In this mode, two bytes are used to indicate the location of each sprite, instead of one. That is, the list of sprite pointers will be 16 bytes long, instead of 8 bytes long as on the VIC-II/III. When SPRPTR16 is enabled, the location of the sprite pointers should always be set explicitly via the SPRPTRADR registers. For example, to position the sprite pointers at location 800 – 815, you could use something like the following. Note that a little gymnastics is required to keep the SPRPTR16 bit unchanged, and also to work around the AND binary operator not working with values greater than 65535:

```
IFPEEK(53272)<32THENPOKE53295,ASC("G"):POKE53295,ASC("S"):REM ENABLE C65+MEGA65
POKE53356,(800-INT(800/65536)*65536) AND 255
POKE53357,INT(800/256)AND255
POKE53358,(PEEK(53358)AND128)+INT(800/65536)
```

The location of each sprite image remains a multiple of 64 bytes, thus allowing for upto 65,536 unique sprite images to be used at any point in time, if the system is equipped with sufficient RAM (4MB or more). In this mode, the VIC-II 16KB banking is ignored, and the location of sprite data is simply $64 \times$ the pointer value. For example, to have the data for a sprite at \$C000 (49152 decimal), this would be sprite location 768, because 49152 divided by 64 = 768. We then need to split 768 into high and low bytes, to set the two pointer bytes: $768 = 256 \times 3$, with remainder 0, so this would require the two sprite pointer bytes to be 0 (low byte, which comes first) and 3 (high byte). Thus if the sprite pointers were located at \$7F8 (2040 decimal), setting the first sprite to sprite image 768 could be done with something like:

```
POKE2040,INT(768/256)
POKE2041,768-256*INT(768/256)
```

HOT REGISTERS

Because of the availability of precise vernier registers to set a wide range of video parameters directly, \$D011 (53265 decimal), \$D016 (53272 decimal) and other VIC-II and VIC-III video mode registers are implemented as virtual registers: by default, writing to any of these results in computed consistent values being applied to all of the relevant vernier registers. This means that writing to any of these virtual registers will reset the video mode. Thus some care has to be taken when using new VIC-IV features to not touch any of the "hot" VIC-II and VIC-III registers.

The "hot" registers to be careful with are:

\$D011, \$D016, \$D018, \$D031 (53265, 53272, 53274 and 53287 decimal) and the VIC-II bank bits of \$DD00 (56576 decimal).

If you write to any of those, various VIC-IV registers will need to be re-written with the values you wish to maintain.

This “hot” register behaviour is intended primarily for legacy software. It can be disabled by clearing the HOTREG signal (bit 7 of \$D05D, 53341 decimal).

NEW MODES

Why the new VIC-IV modes are Character and Bitmap modes, not Bitplane modes

The new VIC-IV video modes are derived from the VIC-II character and bitmap modes, rather than the VIC-III bitplaner modes. This decision was based on several realities of programming a memory-constrained 8-bit home computer:

1. Bitplanes require that the same amount of memory is given to each area on screen, regardless of whether it is showing empty space, or complex graphics. There is no way with bitplanes to reuse content from within an image in another part of the image. However, most C64 games use highly repetitive displays, with common elements appearing in various places on the screen, of which Boulder Dash and Super Giana Sisters would be good examples.
2. Bitplanes also make it difficult to update a display, because every pixel is unique, in that there is no way to make a change, for example to the animation in an onscreen element, and have it take effect in all places at the same time. The diamond animations in Boulder Dash are a good example of this problem. The requirement to modify multiple separate bytes in each bitplane create an increased computational burden, which is why there were calls for the Amiga AAA chipset to include so-called “chunky” modes, rather than just bitplanar modes. While the Display Address Translator (DAT) and DMAgic of the C65 provide some relief to this problem, the relief is only partial.
3. Scrolling using the C65 bitplanes requires copying the entire bitplane, as the hardware support for smooth scrolling does not extend to changing the bitplane source address in a fine manner. Even using the DMAgic to assist, scrolling a 320×200 256-colour display requires 128,000 clock cycles in the best case (reading and writing $320 \times 200 = 64000$ bytes). At 3.5MHz on the C65 this would require about 36 milli-seconds, or about 2 complete video frames. Thus for smooth scrolling of such a dis-

play, a double buffered arrangement would be required, which would consume 128,000 of the 131,072 bytes of memory.

In contrast, the well known character modes of the VIC-II are widely used in games, due to their ability to allow a small amount of screen memory to select which 8×8 block of pixels to display, allowing very rapid scrolling, reduced memory consumption, and effective hardware acceleration of animation of common elements. Thus the focus of improvements in the VIC-IV has been on character mode. As bitmap mode on the VIC-II is effectively a special case of character mode, with implied character numbers, it comes along free for the ride on the VIC-IV, and will only be mentioned in the context of a very few bitmap-mode specific improvements that were trivial to make, and it thus seemed foolish to not implement, in case they find use.

Displaying more than 256 unique characters via “Super-Extended Attribute Mode”

The primary innovation is the addition of Super-Extended Attribute Mode. The VIC-II already uses 12 bits per character: Each 8×8 cell is defined by 12 bits of data: 8 bits of screen RAM data, by default from \$0400 – \$07E7 (1024 – 2023 decimal), indicating which characters to show, and 4 bits of colour data from the 1K nybl colour RAM at \$D800 – \$DBFF (55296 – 56319 decimal). The VIC-III of the C65 uses 16 bits, as the colour RAM is now 8 bits, instead of 4, with the extra 4 bits of colour RAM being used to support attributes (blink, bold, underline and reverse video). It is recommended to revise how this works, before reading the following. A good introduction to the VIC-II text mode can be found in many places, for example, [??](#). Super-Extended Attribute mode doubles the number of bits per used to describe each character from the VIC-III's 16, to 32: Two bytes of screen RAM and two bytes of colour/attribute RAM.

Super-Extended Attribute Mode is enabled by setting bit 0 in \$D054 (53332 decimal) (remember to first enable VIC-IV mode, to make this register accessible). When this bit is set, two bytes are used for each of the screen memory and colour RAM for each character shown on the display. Thus, in contrast to the 12 bits of information that the C64 uses per character, and the 16 bits that the VIC-III uses, the VIC-IV has 32 bits of information. How those 32 bits are used varies slightly among the particular modes. The default is as follows:

Bit(s)	Function
Screen RAM byte 0	Lower 8 bits of character number, the same as the VIC-II and VIC-III
Screen RAM byte 1, bits 0 - 4	Upper 5 bits of character number, allowing addressing of 8,192 unique characters
Screen RAM byte 1, bits 5 - 7	Trim pixels from right side of character (bits 0 - 2)
Colour RAM byte 0, bit 7	Vertically flip the character
Colour RAM byte 0, bit 6	Horizontally flip the character
Colour RAM byte 0, bit 5	Alpha blend mode (leave 0, discussed later)
Colour RAM byte 0, bit 4	GOTO X (allows repositioning of characters along a raster via the Raster-Rewrite Buffer, discussed later)
Colour RAM byte 0, bits 3	If set, Full-Colour characters use 4 bits per pixel and are 16 pixels wide (less right side trim bits), instead of using 8 bits per pixel, and being the usual 8 pixels wide
Colour RAM byte 0, bits 2	Trim pixels from right side of character (bit 3)
Colour RAM byte 0, bits 0 - 1	Number of pixels to trim from top or bottom of character
Colour RAM byte 1, bits 0 - 3	Low 4 bits of colour of character
Colour RAM byte 1, bit 4	Hardware blink of character (if VIC-III extended attributes are enabled)
Colour RAM byte 1, bit 5	Hardware reverse video enable of character (if VIC-III extended attributes are enabled)*
Colour RAM byte 1, bit 6	Hardware bold attribute of character (if VIC-III extended attributes are enabled)*
Colour RAM byte 1, bit 7	Hardware underlining of character (if VIC-III extended attributes are enabled)

* Enabling BOLD and REVERSE attributes at the same time on the MEGA65 selects an alternate palette, effectively allowing 512 colours on screen, but each 8×8 character can use colours only from one 256 colour palette.

We can see that we still have the C64 style bottom 8 bits of the character number in the first screen byte. The second byte of screen memory gets five extra bits for that, allowing $2^{13} = 8,192$ different characters to be used on a single screen. That's more than enough for unique characters covering an 80×50 screen (which is possible to create with the VIC-IV). The remaining bits allow for trimming of the character. This allows for variable width characters,

which can be used to do things that would not normally be possible, such as using text mode for free horizontal placement of characters (or parts thereof). This was originally added to provide hardware support for proportional width fonts.

For the colour RAM, the second byte (byte 1) is the same as the C65, i.e., the lower half providing four bits of foreground colour, as on the C64, plus the optional VIC-III extended attributes. The C65 specifications document describes the behaviour when more than one of these are used together, most of which are logical, but there are a few combinations that behave differently than one might expect. For example, combining bold with blink causes the character to toggle between bold and normal mode. Bold mode itself is implemented by effectively acting as bit 4 of the foreground colour value, causing the colour to be drawn from different palette entries than usual.

The C65 / VIC-III attributes (and the use of 256 colour 8-bit values for various VIC-II colour registers is enabled by setting bit 5 of \$D031 (53297 decimal). Therefore this is highly recommended when using the VIC-IV mode, as otherwise certain functions will not behave as expected.) Note that BOLD+REVERSE together has the meaning of selecting an alternate palette on the MEGA65, which differs from the C65.

Many effects are possible due to Super-Extended Attribute Mode. A few possibilities are explained in the following sub-sections

Variable Width Fonts

There are 4 bits that allow trimming pixels from the right edge of characters when they are displayed. This has the effect of making characters narrower. This can be useful for making more attractive text displays, where narrow characters, such as “i” take less space than wider characters, such as “m”, without having to use a bitmap display. This feature can be used to make it very efficient to display such variable-width text displays – both in terms of memory usage and processing time.

This feature can be combined with full-colour text mode, alpha blending mode and 4-bits per pixel mode to allow characters that consist of 15 levels of intensity between the background and foreground colour, and that are up to 16 pixels wide. Further, the GOTO bit can be used to implement negative kerning, so that character pairs like A and T do not have excessive white space between them when printed adjacently. The prudent use of these features can result in highly impressive text display, similar to that on modern systems, but that are still efficient enough to be implemented on a relatively constrained

system such as the MEGA65. The “MegaWAT!?” presentation software for the MEGA65 uses several of these features to produce its attractive anti-aliased proportional text display on slides.

XXX Example program

Raster-Rewrite Buffer

If the GOTO bit is set for a character in Super-Extended Attribute Mode, instead of painting a character, the position on the raster is back-tracked (or advanced forward to) the pixel position specified in the low 10 bits of the screen memory bytes. If the vertical flip bit is set, then this has the alternate meaning of preventing the background colour from being painted. This combination can be used to print text material over the top of other text material, providing a crude supplement to the 8 hardware sprites. The amount of material is limited only by the raster time of the VIC-IV. Some experimentation will be required to determine how much can be achieved in PAL and NTSC modes.

This ability to draw multiple layers of text and graphics is highly powerful. For example, it can be used to provide multiple overlapping layers of separately scrollable graphics. This gives many of the advantages of bitplane-based playfields on other computers, such as the Amiga, but without the disadvantages of bitplanes.

XXX Example program

SPRITES

VIC-II/III Sprite Control

The control of sprites for C64 / VIC-II/III compatibility is unchanged from the C64. The only practical differences are very minor. In particular the VIC-IV uses ring-buffer for each sprites data when rendering a raster. This means that a sprite can be displayed multiple times per raster line, thus potentially allowing for horizontal multiplexing.

Extended Sprite Image Sets

On the VIC-II and VIC-III, all sprites must draw their image data from a single 16KB region of memory at any point in time. This limits the number of different sprite images to 256, because each sprite image occupies 64 bytes. In practice, the same 16KB region must also contain either bitmap, text or bitplane data, considerably reducing the number of sprite images that can be used at the same time.

The VIC-IV removes this limitation, by allowing sprite data to be placed anywhere in memory, although still on 64-byte boundaries. This is done by setting the SPRPTR16 signal (bit 7, \$D06E, decimal 53358), which tells the VIC-IV to expect two bytes per sprite pointer instead of one. These addresses are then absolute addresses, and ignore the 16KB VIC-II bank selection logic. Thus 16 bytes are required instead of 8 bytes. The list of pointers can also be placed anywhere in memory by setting the SPRPTRADR (\$D06C – \$D06D, 53356 – 53357 decimal) and SPRPTRBNK signals (bits 0 – 6, \$D06E, 53358 decimal). This allows for sprite data to be located anywhere in the first 4MB of RAM, and the sprite pointer list to be located anywhere in the first 8MB of RAM. Note that typical installations of the VIC-IV have only 384KB of connected RAM, so these limitations are of no practical effect. However, the upper bits of the SPRPTRBNK signal should be set to zero to avoid forward-compatibility problems.

One reason for supporting more sprite images is that sprites on the VIC-IV can require more than one 64 byte image slot. For example, enabling Extra-Wide Sprite Mode means that a sprite will require $8 \times 21 = 168$ bytes, and will thus occupy four VIC-II style 64 byte sprite image slots. If variable height sprites are used, this can grow to as much as $8 \times 255 = 2,040$ bytes per sprite.

Variable Sprite Size

Sprites can be one of three widths with the VIC-IV:

1. Normal VIC-II width (24 pixels wide).
2. Extra Wide, where 64 bits (8 bytes) of data are used per raster line, instead of the VIC-II's 24. This results in sprites that are 64 pixels wide, unless Full-Colour Sprite Mode is selected for a sprite, in which case the sprite will be $64 = 16$ pixels wide.
3. Tiled mode, where the sprite is drawn repeatedly until the end of the raster line.

To enable a sprite to be 64 pixels (or 16 pixels if in Full-Colour Sprite Mode), set the corresponding bit for the sprite in the SPRX64EN register at (\$D057, 53335 decimal).

Similarly, sprites can be various heights: Sprites will be either the 21 pixels high of the VIC-II, or if the corresponding bit for the sprite is enabled in the SPRHGTEN signal (\$D055, 53333 decimal), then that sprite will be the number of pixels tall that is set in the SPRHGT register (\$D056, 53334 decimal).

Variable Sprite Resolution

By default, sprites are the same resolution as on the VIC-II, i.e., each sprite pixel is two physical pixels wide and high. However, sprites can be made to use the native resolution, where sprite pixels are one physical pixel wide and/or high. This is achieved by setting the relevant bit for the sprite in the SPRENV400 (\$D076, 53366 decimal) registers to increase the vertical resolution on a sprite-by-sprite basis. The horizontal resolution for all sprites is either the normal VIC-II resolution, or if the SPR640 signal is set (bit 4 of \$D054, 53332 decimal), then sprites will have the same horizontal resolution as the physical pixels of the display.

Sprite Palette Bank

The VIC-IV has four palette banks, compared with the single palette bank of the VIC-III. The VIC-IV allows the selection of separate palette banks for bitmap/text graphics and for sprites. This makes it easy to have very colourful displays, where the sprites have different colours to the rest of the display, or to use palette animation to achieve interesting visual effects in sprites, without disturbing the palette used by other elements of the display.

The sprite palette bank is selected by setting the SPRPALSEL signal in bits 2 and 3 of the register \$D070 (53360 decimal). It is possible to set this to the same bank as the bitmap/text display, or to select a different palette bank. Palette bank selection takes effect immediately. Don't forget that to be able to modify a palette, you have to also bank it to be the palette accessible via the palette bank registers at \$D100 - \$D3FF by setting the MAPEDPAL signal in bits 6 and 7 of \$D070.

Full-Colour Sprite Mode

In addition to monochrome and multi-colour modes, the VIC-IV supports a new full-colour sprite mode. In this mode, four bits are used to encode each sprite pixel. However, unlike multi-colour mode where pairs of bits encode pairs of pixels, in full-colour mode the pixels remain at their normal horizontal resolution. The colour zero is considered transparent. If you wish to use black in a full-colour sprite, you must configure the palette bank that is selected for sprites so that one of the 15 colours for the specific sprite encodes black.

Full-colour sprite mode is selectable for each sprite by setting the appropriate bit in the SPR16EN register (\$D06B, 53355 decimal).

To enable the eight sprites to have 15 unique colours each, the sprite colour is drawn using the palette entry corresponding to: $spritenumber \times 16 + nyblvalue$, where *spritenumber* is the number of the sprite (from 0 to 7), and *nyblvalue* is the value of the half-byte that contains the sprite data for the pixel. In addition, if bitplane mode is enabled for this sprite, then 128 is added to the colour value, which makes it easy to switch between two colour schemes for a given sprite by changing only one bit in the SPRBPMEN register.

Because Full-Colour Sprite Mode requires four bits per pixel, sprites will be only six pixels wide, unless Extra Wide Sprite Mode is enabled for a sprite, in which case the sprite will be 16 pixels wide. Tiled Mode also works with Full-Colour Sprite Mode, and will result in the 16 full-colour pixels of the sprite being repeated until the end of the raster line.

D030	53296	-							C128FAST

- **BLNK** disable display
- **BMM** bitmap mode
- **BORDERCOL** display border colour (16 colour)
- **BSP** sprite background priority bits
- **C128FAST** 2MHz select (for C128 2MHz emulation)
- **CB** character set address location (\times 1KiB)
- **CSEL** 38/40 column select
- **ECM** extended background mode
- **ISBC** sprite:bitmap collision indicate or acknowledge
- **ISSC** sprite:sprite collision indicate or acknowledge
- **LPX** Coarse horizontal beam position (was lightpen X)
- **LPY** Coarse vertical beam position (was lightpen Y)
- **MC1** multi-colour 1 (16 colour)
- **MC2** multi-colour 2 (16 colour)
- **MC3** multi-colour 3 (16 colour)
- **MCM** Multi-colour mode
- **MISBC** mask sprite:bitmap collision IRQ
- **MISSC** mask sprite:sprite collision IRQ
- **MRIRQ** mask raster IRQ
- **RC** raster compare bit 8
- **RIRQ** raster compare indicate or acknowledge
- **RSEL** 24/25 row select
- **RST** Disables video output on MAX Machine(tm) VIC-II 6566. Ignored on normal C64s and the MEGA65
- **S0X** sprite 0 horizontal position
- **S0Y** sprite 0 vertical position
- **S1X** sprite 1 horizontal position
- **S1Y** sprite 1 vertical position
- **S2X** sprite 2 horizontal position

- **S2Y** sprite 2 vertical position
- **S3X** sprite 3 horizontal position
- **S3Y** sprite 3 vertical position
- **S4X** sprite 4 horizontal position
- **S4Y** sprite 4 vertical position
- **S5X** sprite 5 horizontal position
- **S5Y** sprite 5 vertical position
- **S6X** sprite 6 horizontal position
- **S6Y** sprite 6 vertical position
- **S7X** sprite 7 horizontal position
- **S7Y** sprite 7 vertical position
- **SBC** sprite/foreground collision indicate bits
- **SCM** sprite multicolour enable bits
- **SCREENCOL** screen colour (16 colour)
- **SE** sprite enable bits
- **SEXX** sprite horizontal expansion enable bits
- **SEXY** sprite vertical expansion enable bits
- **SPR0COL** sprite 0 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR1COL** sprite 1 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR2COL** sprite 2 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR3COL** sprite 3 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR4COL** sprite 4 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR5COL** sprite 5 colour / 16-colour sprite transparency colour (lower nybl)
- **SPR6COL** sprite 6 colour / 16-colour sprite transparency colour (lower nybl)

- **SPR7COL** sprite 7 colour / 16-colour sprite transparency colour (lower nybl)
- **SPRMC0** Sprite multi-colour 0 (always 256 colour)
- **SPRMC1** Sprite multi-colour 1 (always 256 colour)
- **SSC** sprite/sprite collision indicate bits
- **SXMSB** sprite horizontal position MSBs
- **VS** screen address (\times 1KiB)
- **XSCL** horizontal smooth scroll
- **YSCL** 24/25 vertical smooth scroll

- **B7PIX** Display Address Translator (DAT) Bitplane 7 port
- **BORDERCOL** display border colour (256 colour)
- **BPCOMP** Complement bitplane flags
- **BPM** Bit-Plane Mode
- **BPX** Bitplane X
- **BPY** Bitplane Y
- **CRAM2K** Map 2nd KB of colour RAM \$DC00-\$DFFF
- **CROM9** Select between C64 and C65 charset.
- **EXTSYNC** Enable external video sync (genlock input)
- **FAST** Enable C65 FAST mode (3 .5MHz)
- **H1280** Enable 1280 horizontal pixels (not implemented)
- **H640** Enable C64 640 horizontal pixels / 80 column mode
- **HPOS** Bitplane X Offset
- **INT** Enable VIC-III interlaced mode
- **KEY** Write *A5then96* to enable C65/VIC-III IO registers
- **MC1** multi-colour 1 (256 colour)
- **MC2** multi-colour 2 (256 colour)
- **MC3** multi-colour 3 (256 colour)

- **MONO** Enable VIC-III MONO video output (not implemented)
- **PAL** Use PALETTE ROM or RAM entries for colours 0 - 15
- **PALBLUE** blue palette values (reversed nybl order)
- **PALGREEN** green palette values (reversed nybl order)
- **PALRED** red palette values (reversed nybl order)
- **ROM8** Map C65 ROM \$8000
- **ROMA** Map C65 ROM \$A000
- **ROMC** Map C65 ROM \$C000
- **ROME** Map C65 ROM \$E000
- **SCREENCOL** screen colour (256 colour)
- **SPRMC0** Sprite multi-colour 0 (8-bit for selection of any palette colour)
- **SPRMC1** Sprite multi-colour 1 (8-bit for selection of any palette colour)
- **V400** Enable 400 vertical pixels
- **VPOS** Bitplane Y Offset

- **ABTPALSEL** VIC-IV bitmap/text palette bank (alternate palette)
- **ALPHADELAY** Alpha delay for compositor
- **ALPHEN** Alpha compositor enable
- **BBDRPOS** bottom border position
- **BORDERCOL** display border colour (256 colour)
- **BP16ENS** VIC-IV 16-colour bitplane enable flags
- **BTPALSEL** bitmap/text palette bank
- **CHARPTR** Character set precise base address (bits 0 - 7)
- **CHARSTEP** characters per logical text row (LSB)
- **CHR16** enable 16-bit character numbers (two screen bytes per character)
- **CHRCOUNT** Number of characters to display per row
- **CHRPTR** Character set precise base address (bits 15 - 8)
- **CHRXSCL** Horizontal hardware scale of text mode (pixel 120ths per pixel)
- **CHRYSCL** Vertical scaling of text mode (number of physical rasters per char text row)
- **COLPTR** colour RAM base address (bits 0 - 7)
- **FCLRHI** enable full-colour mode for character numbers >\$FF
- **FCLRLO** enable full-colour mode for character numbers <=\$FF
- **FNRASTER** Read physical raster position

- **FNRST** Raster compare source (1=VIC-IV fine raster, 0=VIC-II raster)
- **FNRSTCMP** Raster compare is in physical rasters if set, or VIC-II raster if clear
- **HOTREG** Enable VIC-II hot registers. When enabled, touching many VIC-II registers causes the VIC-IV to recalculate display parameters, such as border positions and sizes
- **HSYNCP** hsync polarity
- **KEY** Write 47then53 to enable C65GS/VIC-IV IO registers
- **MAPEDPAL** palette bank mapped at \$D100-\$D3FF
- **MC1** multi-colour 1 (256 colour)
- **MC2** multi-colour 2 (256 colour)
- **MC3** multi-colour 3 (256 colour)
- **PALEMU** video output pal simulation
- **PALNTSC** NTSC emulation mode (max raster = 262)
- **RASLINE0** first VIC-II raster line
- **RASTERHEIGHT** physical rasters per VIC-II raster (1 to 16)
- **RESERVED**
- **RSTCMP** Raster compare value MSB
- **RSTCOMP** Raster compare value
- **RSTDELEN** Enable raster delay (delays raster counter and interrupts by one line to match output pipeline latency)
- **SCREENCOL** screen colour (256 colour)
- **SCRNPTR** screen RAM precise base address (bits 0 - 7)
- **SIDBDRWD** Width of single side border
- **SMTH** video output horizontal smoothing enable
- **SPR16EN** sprite 16-colour mode enables
- **SPR640** Sprite H640 enable;
- **SPRALPHAVAL** Sprite alpha-blend value
- **SPRBPMEN** Sprite bitplane-modify-mode enables
- **SPRENALPHA** Sprite alpha-blend enable

- **SPRENV400** Sprite V400 enables
- **SPRHGHT** Sprite extended height size (sprite pixels high)
- **SPRHGTEN** sprite extended height enable (one bit per sprite)
- **SPRMC0** Sprite multi-colour 0 (8-bit for selection of any palette colour)
- **SPRMC1** Sprite multi-colour 1 (8-bit for selection of any palette colour)
- **SPRPALSEL** sprite palette bank
- **SPRPTR16** 16-bit sprite pointer mode (allows sprites to be located on any 64 byte boundary in chip RAM)
- **SPRPTRADR** sprite pointer address (bits 7 - 0)
- **SPRPTRBNK** sprite pointer address (bits 22 - 16)
- **SPRTILEN** Sprite horizontal tile enables.
- **SPRX64EN** Sprite extended width enables (8 bytes per sprite row = 64 pixels wide for normal sprites or 16 pixels wide for 16-colour sprite mode)
- **SPRXSMSBS** Sprite H640 X Super-MSBs
- **SPRYSMSBS** Sprite V400 Y position super MSBs
- **SRPYMSBS** Sprite V400 Y position MSBs
- **TBDRPOS** top border position
- **TEXTXPOS** character generator horizontal position
- **TEXTYPOS** Character generator vertical position
- **VFAST** C65GS FAST mode (48MHz)
- **VSYNCP** vsync polarity
- **VSYNDEL** VIC-IV VSYNC delay
- **XPOS** Read horizontal raster scan position

CIA 6526 HYPERVISOR REGISTERS

In addition to the standard CIA registers available on the C64 and C65, the MEGA65 provides an additional set of registers that are visible only when the system is in Hypervisor Mode. These additional registers allow the internal state of the CIA to be more fully extracted when freezing, thus allowing more programs to function correctly after being frozen. They are not visible when using the MEGA65 normally, and can be safely ignored by programmers who are not programming the MEGA65 in Hypervisor Mode.

- **CHARSZ** UART character size: 00=8, 01=7, 10=6, 11=5 bits per byte
- **DATA** UART data register (read or write)
- **DIVISOR** UART baud rate divisor (16 bit). Baud rate = 7.09375MHz / DIVISOR, unless MEGA65 fast UART mode is enabled, in which case baud rate = 80MHz / DIVISOR
- **FRMERR** UART RX framing error flag (clear by reading \$D600)
- **IFRXIRQ** UART interrupt flag: IRQ on RX (not yet implemented on the MEGA65)
- **IFRXNMI** UART interrupt flag: NMI on RX (not yet implemented on the MEGA65)
- **IFTXIRQ** UART interrupt flag: IRQ on TX (not yet implemented on the MEGA65)
- **IFTXNMI** UART interrupt flag: NMI on TX (not yet implemented on the MEGA65)
- **IMRXIRQ** UART interrupt mask: IRQ on RX (not yet implemented on the MEGA65)
- **IMRXNMI** UART interrupt mask: NMI on RX (not yet implemented on the MEGA65)
- **IMTXIRQ** UART interrupt mask: IRQ on TX (not yet implemented on the MEGA65)
- **IMTXNMI** UART interrupt mask: NMI on TX (not yet implemented on the MEGA65)
- **PTYEN** UART Parity enable: 1=enabled

- **PTYERR** UART RX parity error flag (clear by reading \$D600)
- **PTYEVEN** UART Parity: 1=even, 0=odd
- **RXEN** UART enable receive
- **RXOVRRUN** UART RX overrun flag (clear by reading \$D600)
- **RXRDY** UART RX byte ready flag (clear by reading \$D600)
- **SYNCMOD** UART synchronisation mode flags (00=RX & TX both async, 01=RX sync, TX async, 1x=TX sync, RX async (unused on the MEGA65))
- **TXEN** UART enable transmit

- **ASCIKEY** Last key press as ASCII (hardware accelerated keyboard scanner). Write to clear event ready for next.
- **BASHDDR** Data Direction Register (DDR) for \$D60D bit bashing port.
- **CONN41** Internal 1541 drive connect (1=connect internal 1541 drive to IEC bus)
- **HDSCL** HDMI SPI control interface SCL clock
- **HDSPI** HDMI SPI control interface SDA data line
- **KEYLEFT** Directly read C65 Cursor left key
- **KEYUP** Directly read C65 Cursor up key
- **KSCNRATE** Physical keyboard scan rate (\$00=50MHz, \$FF= 200KHz)
- **LJOYA** Rotate inputs of joystick A by 180 degrees (for left handed use)
- **LJOYB** Rotate inputs of joystick B by 180 degrees (for left handed use)
- **MALT** ALT key state (hardware accelerated keyboard scanner).
- **MCTRL** CTRL key state (hardware accelerated keyboard scanner).
- **MLSHFT** Left shift key state (hardware accelerated keyboard scanner).
- **MMEGA** MEGA/C= key state (hardware accelerated keyboard scanner).
- **MRSHT** Right shift key state (hardware accelerated keyboard scanner).
- **MSCRL** NOSCR L key state (hardware accelerated keyboard scanner).
- **OSKALT** Display alternate on-screen keyboard layout (typically dial pad for MEGA65 telephone)
- **OSKEN** Enable display of on-screen keyboard composited overlay
- **OSKTOP** 1=Display on-screen keyboard at top, 0=Display on-screen keyboard at bottom of screen.
- **OSKXPOS** Set on-screen keyboard X position (x4 640H pixels)
- **OSKYPOS** Set on-screen keyboard Y position (x4 physical pixels)
- **OSKZEN** Display hardware zoom of region under first touch point for on-screen keyboard
- **OSKZON** Display hardware zoom of region under first touch point always
- **PHYJOY** Enable physical joystick input
- **PHYKEY** Enable physical keyboard input

- **PORTF** PMOD port A on FPGA board (data) (Nexys4 boards only)
- **PORTFDDR** PMOD port A on FPGA board (DDR)
- **POTAX** Read Port A paddle X, without having to fiddle with SID/CIA settings.
- **POTAY** Read Port A paddle Y, without having to fiddle with SID/CIA settings.
- **POTBX** Read Port B paddle X, without having to fiddle with SID/CIA settings.
- **POTBY** Read Port B paddle Y, without having to fiddle with SID/CIA settings.
- **PS2JOY** Enable PS/2 / USB keyboard simulated joystick input
- **PS2KEY** Enable ps2 keyboard/joystick input
- **RST41** Internal 1541 drive reset (1=reset, 0=operate)
- **SDBSH** Enable SD card bitbash mode
- **SDCLK** SD card SCLK
- **SDCS** SD card CS_BO
- **SDDATA** SD card MOSI/MISO
- **UFAST** C65 UART BAUD clock source: 1 = 7.09375MHz, 0 = 80MHz (VIC-IV pixel clock)
- **VIRTKEY1** Set to \$7F for no key down, else specify virtual key press.
- **VIRTKEY2** Set to \$7F for no key down, else specify 2nd virtual key press.
- **VIRTKEY3** Set to \$7F for no key down, else specify 3rd virtual key press.
- **VRTKEY** Enable virtual/snythetic keyboard input
- **WGTKEY** Enable widget board keyboard/joystick input

APPENDIX

45E100 Fast Ethernet Controller

- **Overview**
- **Memory Mapped Registers**
- **Example Programs**

OVERVIEW

The 45E100 is a new and simple Fast Ethernet controller that has been designed specially for the MEGA65 and for 8-bit computers generally. In addition to supporting 100Mbit Fast Ethernet, it is radically different from other ethernet controllers, such as the RR-NET.

The 45E100 includes dual receive buffers, allowing one frame to be processed while another is receiving. It includes automatic CRC32 checking on reception, and automatic CRC32 generation for transmit, considerably reducing the burden on the processor and allowing for very simple programs. It also supports true full-duplex operation at 100Mbit per second, allowing for total bi-directional throughput exceeding 100Mbit per second. The MAC address is software configurable, and promiscuous mode is supported, as are individual control of the reception of broadcast and multi-cast ethernet frames. The 45E100 also supports both transmit and receive interrupts, allowing greatly improved real-world performance. When especially low latency is required, it is also possible to immediately abort the transmission of the current ethernet frame, so that a higher-priority frame can be immediately sent. These features combine to enable sub-millisecond round trip latencies, which can be of particular value for interactive applications, such as multi-player network games.

Differences to the RR-NET and similar solutions

The RR-NET and other ethernet controllers for the Commodore(tm) line of 8-bit home computers generally use an ethernet controller that was designed for 16-bit PCs, but that also supports a so-called "8-bit mode," which suffers from a number of disadvantages. The primary disadvantages are the lack of working interrupts, and processor intensive access to the ethernet frame buffers. The lack of interrupts forces programs to use polling to check for the arrival of new ethernet frames. This, together with the complexities of accessing the buffers results in an ethernet interface that is very slow, and whose real-world throughput is considerably less than its theoretical 10Mbits per second. Even a Commodore 64 with REU cannot achieve speeds above several tens of kilobytes per second.

In contrast, the 45E100 supports both RX (ethernet frame received) interrupts and TX (ready to transmit) interrupts, freeing the processor from having to poll

the device. Because the 45E100 supports RX interrupts, there is no need for large numbers of receive buffers, which is why the 45E100 requires only two RX buffers to achieve very high levels of performance.

Further, the 45E100 supports direct memory mapping of the ethernet frame buffers, allowing for much more efficient access, including by DMA. Using the MEGA65's integrated DMA controller it is quite possible to achieve transfer rates of several mega-bytes per second – some 100x faster than the RR-NET.

Theory of Operation: Receiving Frames

The 45E100 is simple to operate: To begin receiving ethernet frames, the programmer needs only to clear the RST bit (bit 0 of register \$D6E0) to release the ethernet controller from reset. It will then auto-negotiate connection at the highest available speed, typically 100Mbit, full-duplex. The RXBLKD bit (bit 6 of \$D6E0) should then be checked, and if set, the RXBM (bit 2 of register \$D6E1) bit should be toggled to switch the active and mapped receive buffers, so that the 45E100 knows that the program no longer needs the contents of the previously mapped buffer, and can safely begin receiving an ethernet frame into that buffer.

When the 45E100 receives an ethernet frame, it will assert RXBLKD to indicate that the receive buffer has been filled with an ethernet frame. No further ethernet frames will be received until RXBLKD is cleared again, as described above. This is because the 45E100 has only two receive buffers for ethernet frames: one of which is mapped visible to the processor, and the other which is visible to the 45E100's ethernet engine at any point in time. Toggling RXBM allows toggling between which of the two buffers is mapped and which is ready to receive an ethernet frame. The buffers are 2KiB bytes each. The first two bytes are used to indicate the length of the received frame, and four are consumed by the ethernet CRC32 code, yielding an effective Maximum Transport Unit (MTU) length of 2,042 bytes. The ethernet frame data begins at byte offset 2 in the receive buffer, with the frame length written LSB-first in the first two bytes. The layout of the receive buffers is thus as follows:

HEX	DEC	Length	Description
0000	0	1	The low byte of the length of the received ethernet frame.

continued ...

...continued

HEX	DEC	Length	Description
0001	1	1	The lower four bits contain the upper bits of the length of the received ethernet frame. Bit 4 is set if the received ethernet frame is a multi-cast frame. Bit 5 if it is a broadcast frame. Bit 6 is set if the frame's destination address matches the 45E100's programmed MAC address. Bit 7 is set if the CRC32 check for the received frame failed, i.e., that the frame is either truncated or was corrupted in transit.
0002 - 07FB	2 - 2,043	2,042	The received frame. Frames shorter than 2,042 bytes will begin at offset 2.
07FC - 07FF	2,044 - 2,047	4	Reserved space for holding the CRC32 code during reception. The CRC32 code is, however, always located directly after the received frame, and thus will only occupy this space if the received frame is more than 2,038 bytes long.

Because of the very rapid rate at which Fast Ethernet frames can be received, a programmer should use the receive interrupt feature, enabled by setting RXQEN (bit 7 of \$D6E1). Polling is possible as an alternative, but is not recommended with the 45E100, because at the 100Mbit Fast Ethernet speed, packets can arrive as often as every 10 microseconds. Fortunately, at the MEGA65's 40MHz full speed mode, and using the 20MiB per second DMA copy functionality, it is possible to keep up with such high data rates.

Accessing the Ethernet Frame Buffers

Unlike on the RR-NET, the 45E100's ethernet frame buffers are able to be memory mapped, allowing rapid access via DMA or through assembly language programs. It is also possible to access the buffers from BASIC with some care.

The frame buffers can either be accessed from their natural location in the MEGA65's extended address space at address \$FFDE800 - \$FFDEFFF, or they can be mapped into the normal C64/C65 \$D000 IO address space.

Care must be taken as mapping the ethernet frame buffers into the \$D000 IO address space causes all other IO devices to unavailable during this time. Therefore interrupts MUST be disabled before doing so, whether using BASIC or machine code. Therefore when programming in assembly language or machine code, it is recommended to use the natural location, and to access this memory area using one of the three mechanisms for accessing extended address space, which are described in Appendix ??.

The method of disabling interrupts differs depending on the context in which a program is being written. For programs being written using C64 mode's BASIC 2, the following will work:

```
POKE56333,127: REM DISABLE CIA TIMER IRQS
```

While for C65's BASIC 10, the following must instead be used, because a VIC-III raster interrupt is used instead of a CIA-based timer interrupt:

```
POKE53274,0: REM DISABLE VIC-II/III/IV RASTER IRQS
```

Once this has been done, the IO context for the ethernet controller can be activated by writing \$45 (69 in decimal, equal to the character 'E' in PETSCII)) and \$54 (84 in decimal, equal to the character 'T' in PETSCII) into the VIC-IV's KEY register (\$D02F, 53295 in decimal), e.g.:

```
POKE53295,ASC("E"):POKE53295,ASC("T")
```

At this point, the ethernet RX buffer can be read beginning at location \$D000 (53248 in decimal), and the TX buffer can be written to at the same address. Refer to 'Theory of Operation: Receiving Frames' above for further explanation on this.

Once you have finished accessing the ethernet frame buffer, you can restore the normal C64, C65 or MEGA65 IO context by writing to the VIC-III/IV's KEY register. In most cases, it will make the most sense to revert to the MEGA65's IO context by writing \$47 (71 decimal) in and \$53 (83 in decimal) to the KEY register, e.g.:

```
POKE53295,ASC("G"):POKE53295,ASC("S")
```

Finally, you should then re-enable interrupts, which will again depend on whether you are programming from C64 or C65 mode. For C64 mode:

```
POKE56333,129
```

For C65 mode it would be:

```
POKE53274,129
```

Theory of Operation: Sending Frames

Sending frames is similarly simple: The program must simply load the frame to be transmitted into the transmit buffer, write its length into TXSZLSB and TXSZMSB registers, and then write \$01 into the COMMAND register. The frame will then begin to transmit, as soon as the transmitter is idle. There is no need to calculate and attach an ethernet CRC32 field, as the 45E100 does this automatically.

Unlike for the receiver, there is only one frame buffer for the transmitter (this may be changed in a future revision). This means that you cannot prepare the next frame until the previous frame has already been sent. This slightly reduces the maximum data throughput, in return for a very simple architecture.

Also, note that the transmit buffer is write-only from the processor bus interface. This means that you cannot directly read the contents of the transmit buffer, but must load values “blind”. Finally, the 45E100 allows you to send ethernet

Advanced Features

In addition to operating as a simple and efficient ethernet frame transceiver, the 45E100 includes a number of advanced features, described here.

Broadcast and Multicast Traffic and Promiscuous Mode

The 45E100 supports filtering based on the destination Ethernet address, i.e., MAC address. By default, only frames where the destination Ethernet address matches the ethernet address programmed into the MACADDR1 - MACADDR6 registers will be received. However, if the MCST bit is set, then multicast

ethernet frames will also be received. Similarly, setting the BCST bit will allow all broadcast frames, i.e., with MAC address ff:ff:ff:ff:ff:ff, to be received. Finally, if the NOPROM bit is cleared, the 45E100 disables the filter entirely, and will receive all valid ethernet frames.

Debugging and Diagnosis Features

The 45E100 also supports several features to assist in the diagnosis of ethernet problems. First, if the NOCRC bit is set, then even ethernet frames that have invalid CRC32 values will be received. This can help debug faulty ethernet devices on a network.

If the STRM bit is set, the ethernet transmitter transmits a continuous stream of debugging frames supplied via a special high-bandwidth logging interface. By default, the 45E100 emits a stream of approximately 2,200 byte ethernet frames that contain compressed video provided by a VIC-IV or compatible video controller that supports the MEGA65 video-over-ethernet interface. By writing a custom decoder for this stream of ethernet frames, it is possible to create a remote display of the MEGA65 via ethernet. Such a remote display can be used, for example, to facilitate digital capture of the display of a MEGA65.

The size and content of the debugging frames can be controlled by writing special values to the COMMAND register. Writing \$F1 allows the selection of frames that are 1,200 bytes long. While this reduces the performance of the debugging and streaming features, it allows the reception of these frames on systems whose ethernet controllers cannot be configured to receive frames of 2,200 bytes.

If the STRM bit is set and bit 2 of \$D6E1 is also set, a compressed log of instructions executed by the 45gs02 CPU will instead be streamed, if a compatible processor is connected to this interface. This mechanism includes back-pressure, and will cause the 45gs02 processor to slowdown, so that the instruction data can be emitted. This typically limits the speed of the connected 45gs02 processor to around 5MHz, depending on the particular instruction mix.

Note also that the status of bit 2 of \$D6E1 cannot currently be read directly. This may be corrected in a future revision.

Finally, if the video streaming functionality is enabled, this also enables reception of synthetic keyboard events via ethernet. These are delivered to the MEGA65's Keyboard Complex Interface Adapter (KCIA), allowing full remote interaction with a MEGA65 via its ethernet interface. This feature is primarily intended for development.

MEMORY MAPPED REGISTERS

The 45E100 Fast Ethernet controller is a MEGA65-specific feature. It is therefore only available in the MEGA65 IO context. This is enabled by writing \$53 and then \$47 to VIC-IV register \$D02F. If programming in BASIC, this can be done with:

```
POKE53295,ASC("G"):POKE53295,ASC("S")
```

The 45E100 Fast Ethernet controller has the following registers

COMMAND register values

The following values can be written to the COMMAND register to perform the described functions. In normal operation only the STARTTX command is required, e.g., by performing the following POKE:

```
POKE55012,1
```

EXAMPLE PROGRAMS

Example programs for the ethernet controller exist in imperfect for in the MEGA65 Core repository on github in the src/tests and src/examples directories.

APPENDIX

Flashing the FPGAs and CPLDs in the MEGA65

- **Warning**
- **Flashing the Artix 100T main
FPGA with XILINX VIVADO**
- **Flashing the CPLD in the
MEGA65's Keyboard with
LATTICE DIAMOND**

- **Flashing the MAX10 FPGA on
the MEGA65's Mainboard
with INTEL QUARTUS**

The MEGA65 is an open-source and open-hardware computer. This means you are free, not only to write programs that run on the MEGA65 as a finished computer, but you can use the re-programmable chips in the MEGA65 to turn it into all sorts of other things!

These re-programmable chips are called Field Programmable Gate Arrays (FPGAs) or Complex Programmable Logic Devices (CPLDs), and can implement a wide variety of circuits. They are normally programmed using a programming language like VHDL or Verilog. These are languages that are not commonly encountered by most people. They are also quite different in some ways to “normal” programming languages, and it can take a while to understand how they work, but with some effort and perseverance, many people will be able to do exiting things with them.

Be prepared to install many gigabytes of software on a Linux or Windows PC, before you will be able to write programs for the FPGAs and CPLDs in the MEGA65. Also, “compiling” complex designs can take up to several hours, depending on the speed and memory capacity of your computer! We recommend a computer with at least 8GB RAM, and preferably 16GB if you want to write programs for FPGAs and CPLDs. If on the other hand all you want to do is load programs onto your MEGA65’s FPGAs and CPLDs that other people have written, then most computers running a recent version of Windows or Linux should be able to cope.

WARNING

Before we go any further, we do have to provide a warning about reprogramming the FPGAs and CPLDs in the MEGA65. Re-programming the MEGA65 FPGA can potentially cause damage, or leave your MEGA65 in an unresponsive state from which it is very difficult to recover, i.e., “bricked”. Therefore if you choose to open your MEGA65 and reprogram any of the FPGAs it contains, it is no longer possible to guarantee its correct operation. Therefore in this case we can not reasonably honour the warranty of the device as a computer. You have been warned!

FLASHING THE ARTIX 100T MAIN FPGA WITH XILINX VIVADO

If you choose to proceed, you will need a TE0790-03 JTAG programming module, a functioning installation of Xilinx's Vivado software. This can be done on either Windows or Linux, but in both cases you will need to install any necessary USB drivers. It is also necessary to have dip-switches 1 and 3 in the ON position and dip-switches 2 and 4 in the OFF position on the TE-0790. With your MEGA65 disconnected from the power, the TE-0790 must be installed on the JB1 connector, which is located between the floppy data cable and the audio jack. The gold-plated hole of the TE-0790 must line up with the screw hole below. The mini-USB cable will then connect on the side towards the 3.5" floppy drive. The following image shows the correct position: The TE0790 is surrounded by the yellow box, and the dip-switches by the red box. Dip-switch 1 is the one nearest the floppy data cable.

Connect your non-8-bit computer to the FPGA programming device using a mini-USB cable. Open VIVADO, which can be downloaded from the internet.

To access the Hardware Manager, open a project in VIVADO or create an empty one, if you do not have any projects yet.

In the left column, select "Open Hardware Manager" at the very bottom.

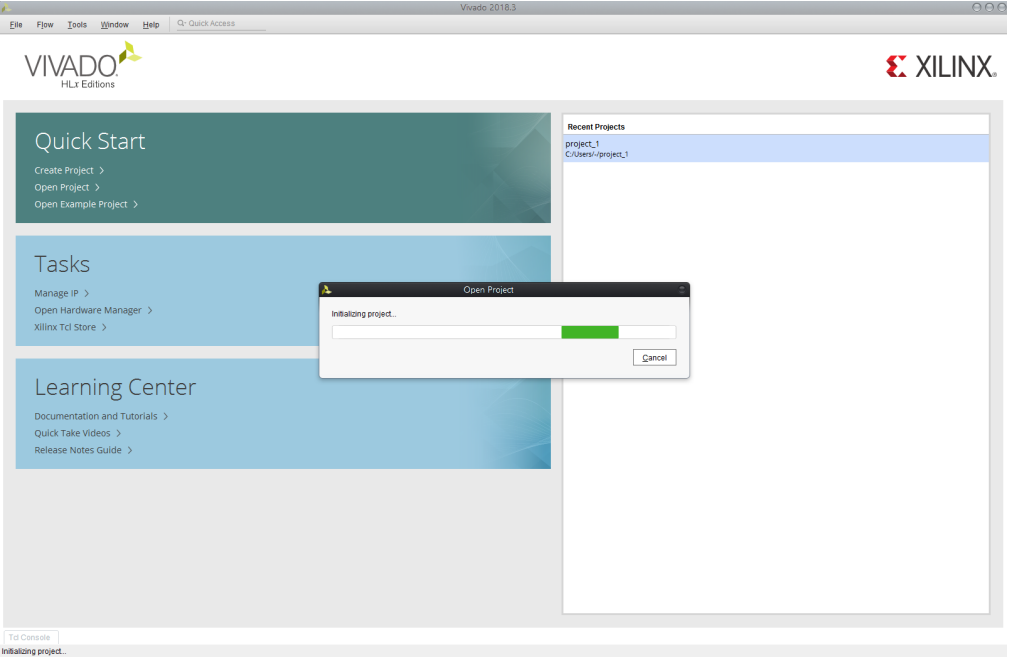

Figure L. 1: Step 1: Open a project in VIVADO

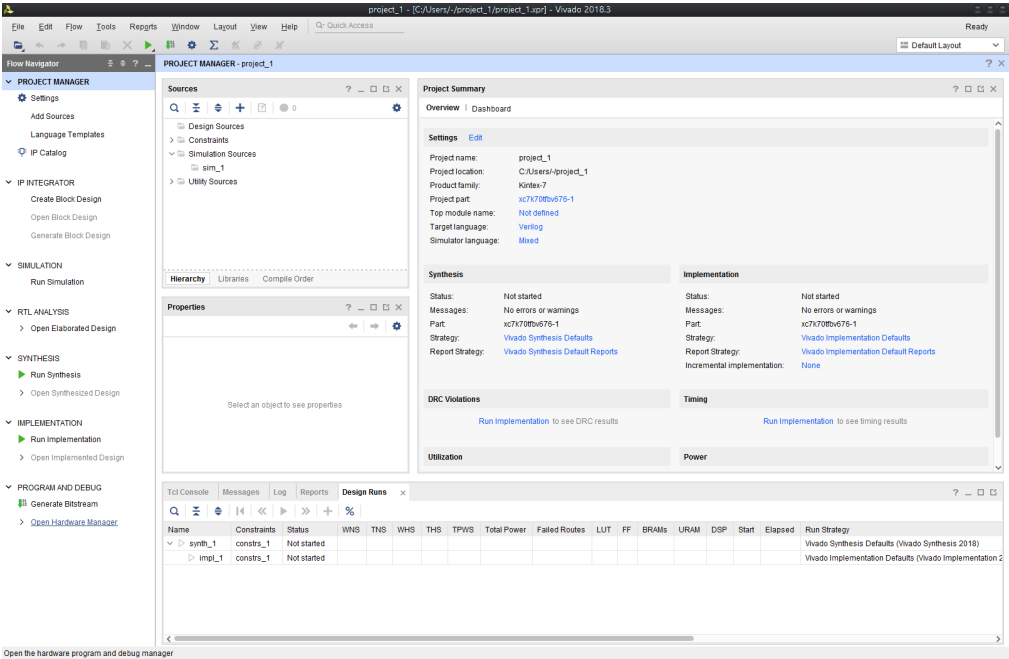

Figure L.2: Step 2: Open Hardware Manager

Figure L.3: Step 3: Connect to FPGA

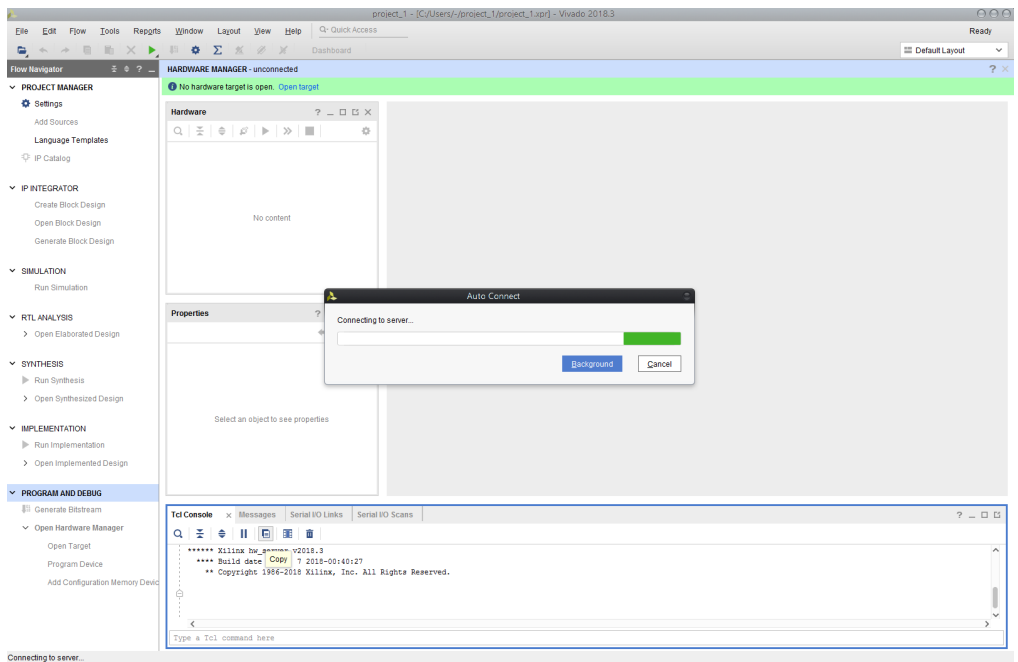

Figure L.4: Step 4: Wait a moment

Under "Hardware Manager", choose "Open Target", then "Auto Connect".

Wait a moment, "Connecting to server..." should automatically close without dropping an error to the console.

Under "Hardware Manager", choose "Add Configuration Memory Device", then "xc7a100t_0".

In the newly opened dialogue, type "S25fl256s" (without quotes), then select "s25fl256sxxxxxx0-spi-x1_x2_x4" (the upper one) and click "OK".

In the next dialogue, choose your local Configuration file, namely a bitstream with file suffix ".mcs". Leave all other parameters as they are (see L.7).

Patiently wait for the programming to finish. This can take several minutes as the Vivado software erases and then reprograms the flash memory that is used to initialise the FPGA on power-up.

If your screen looks like L.9, your new bistream has been successfully flashed into the Artix 100T FPGA!

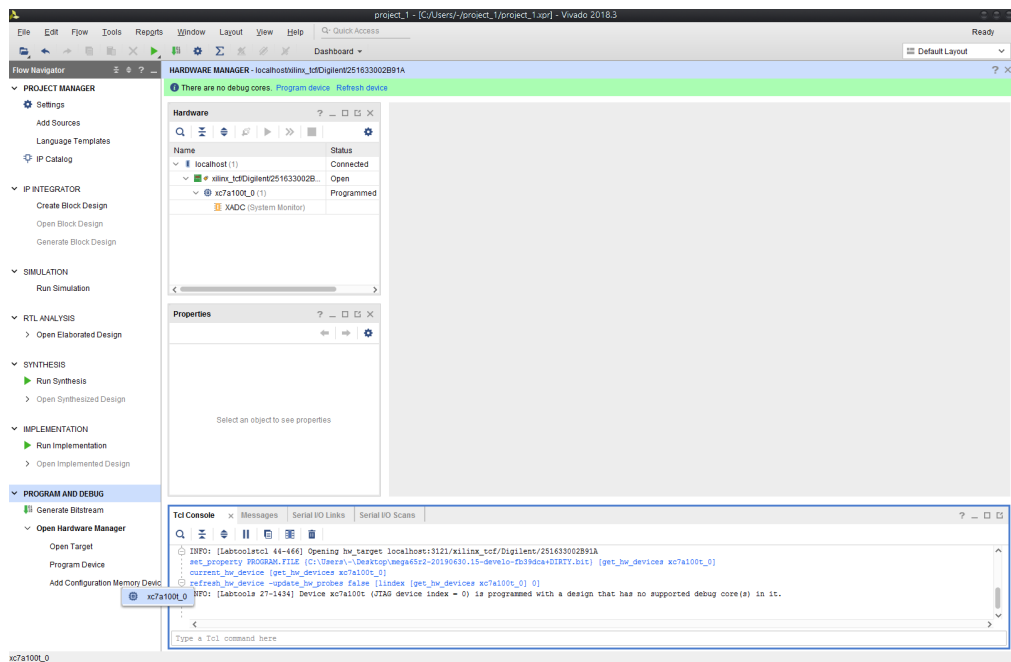

Figure L.5: Step 5: Add Configuration Memory Device

Figure L.6: Step 6: Select Memory Part

Figure L.7: Step 7: Set programming options

Figure L.8: Step 8: Programming in progress

Figure L.9: Step 9: Programming successful

Figure L.10: Step 10: Reflashing the FPGA

If you want to repeat the process, you might find the "Add Configuration Memory Device" option in step 5 greyed out. Instead, select "s25fl256xxxxxx0-spi-x1_x2_x4" in the "Hardware" window, press right mouse button and select "Program Configuration Memory Device" to flash.

M

Supporters & Donors

- **Organisations**
- **Volunteers**
- **Individual Donors**

The MEGA65 would not have been possible to create without the generous support of many organisations and individuals.

We are still compiling these lists, so appologies if we haven't included you yet. If you know anyone we have left out, please let us know, so that we can recognise the contribution of everyone who has made the MEGA65 possible, and into the great retro-computing project that it has become.

ORGANISATIONS

- **M.E.G.A. Museum of Electronic Games and Art, e.V., Germany**
EVERYTHING
